The foregoing directions will, I hope, enable many persons successfully to grow plants, who have hitherto been deterred by fears of failure; the aim of the writer in these articles having been to give the most essential directions in the simplest language, more than to introduce any novelty in treatment. Of course, there are many other plants which will grow in windows which have not been mentioned; but if the plants whose treatment has been here described are successfully grown by the aid of these directions, any other plant that is not unsuitable on account of its delicacy or size, may be tried with a fair prospect of success.

EFFECTS OF POSTURE ON RESPIRATION.

Dr. Edward Smith, one of the sanitary commissioners of the Privy Council, says:—In a long series of experiments which I have made with a view to determine the effect of posture and exertion over the quantity of air inspired in any period, and consequently over the movements of the chest, it was shown that only in the lying posture was it less than the sitting posture; and that the difference between the amount in the latter and that when walking at the moderate rate of three miles per hour was no less than three times of that in the sitting posture. The following table gives the result of this series in many modes of exertion, all compared with the amount of the respiration in the lying posture as the standard:—

The effect in the lying posture being	1·00
That of the sitting posture is	1·18
Reading aloud and singing, each	1·26
The standing posture	1·33
Railway travelling in the 1st class	1·40
Ditto 2nd class	1·5
Ditto upon the engine at 20 to 30 miles per hour	1·52
Ditto upon the engine at 50 to 60 miles per hour	1·55
Ditto 3rd class	1·58
Ditto upon the engine (average of all speeds)	1·58
Ditto upon the engine at 40 to 50 miles	1·61
Ditto upon the engine at 30 to 40 miles	1·64
Walking in the sea	1·65
Ditto on land at one mile per hour	1·9

All the above have an influence exceeding, but not the double of that of, the lying posture.

Riding on horseback at the walking pace	2·2
Walking at two miles per hour	2·76

These have been two to three times the influence of the lying posture.

Riding on horseback at the cantering pace	3·16
Walking at three miles per hour	3·0
Ditto ditto ditto	3·22
Rowing	3·33
Descending steps at 640 yards per hour	3·43
Walking at three miles per hour and carrying 34 lb.	3·5
Walking at three miles per hour and carrying 62 lb.	3·84

These have an influence from three to four times greater than that of the lying posture.

Riding on horseback at the trotting pace	4·05
Swimming	4·33
Ascending steps at 640 yards per hour	4·4
Walking at three miles per hour and carrying 118 lb.	4·75
Walking at four miles per hour	5·0

These have an influence from four to five times that of the lying posture.

Lastly.—The tread-wheel	5·5
Running at six miles per hour	7·9

Valuable Halfpence.—A curious kind of industry has lately sprung up in France. Two-sous pieces, struck in 1852, are now being purchased, principally by silversmiths, for five sous each. It appears that, in 1852, one of the workmen at the Mint let fall by accident into the caldron filled with copper an ingot of gold. Fearing that he would be discharged if the accident became known, he concealed it, and the two-sous pieces were struck off. It was only after the ingot was missed that the matter came out. The secret was kept for some time, but it is now well known to the public, and everybody is on the look-out for the coins in question.

Processes of the Arts and Manufactures.

LEATHER MANUFACTURE.

TANNING.—HARD AND SOFT LEATHERS—VARIOUS PROCESSES OF TANNING—TAWING—CURRYING—THEORY OF TANNING—EMPLOYMENT OF THE RESIDUES OF THE MANUFACTURE OF LEATHER.

The leather manufacture is a very extensive and important branch of British industry, only inferior in value and extent to cotton, wool, and iron, if it be not equal, or even superior, to the latter. Its extent is not so apparent as that of the other manufactures named, for the reason that, while they are centralised in a limited area, the manufacture of leather is carried on in most large towns throughout the kingdom. It is now impossible to arrive at correct data as to the annual value of the leather products of this country at the present day; but it may fairly be estimated at £25,000,000, employing over 300,000 persons, whose wages may be set down at £12,000,000 annually. The employment of the skins of mammiferous animals for clothing, coverings of the feet, and a host of domestic and manufacturing purposes, has been common in all ages and among all nations; but, nevertheless, it must be admitted that modern industry alone has succeeded in giving to these products the special qualities for which they are so justly prized.

The preservation and preparation of skins rests, generally, upon two distinct branches of industry—distinct as to process, similar as to aim. The first is applied exclusively to coarse leather (hides of the calf, ox, and horse): its object is the special action which *tan* or oak-bark exercises upon the skins—this is the art of *tanning*. The second, applicable only to small skins (those of the sheep, goat, young calf, &c.), substitutes for the slow processes of tanning the more rapid and combined action of certain chemical compounds—such as alum, sea-salt, &c. This is *tawing*.

This distinction is not, however, always preserved. In some countries the *tawers* treat small skins with warm solutions of tan; but, in fact, the theory of the different processes is analogous, and whether *tannin* or a mineral salt be employed, the aim proposed is still the same. In either case we seek, with the organic matter of albumenoid nature which constitutes the skin of mammiferous animals, to form an imputrescible, insoluble, inelastic compound—the new properties and indestructibility of which, by numerous agents, are valuable in a host of applications.

As a necessary consequence of the operations of the tanner, or the tawer, is a third manufacture, that of *currying*; for the skins, after the manipulations intended to convert them into imputrescible products, have not yet acquired the physical qualities which constitute their chief excellence. The *currier* undertakes to give to the skins, by *oiling* or *greasing*, *fulling*, *airing*, and *dyeing*, if desired, the suppleness, grain, and colour required in the various purposes to which skins and leather are applied.

Manufacture of Sole-Leather.—The hides or skins of the ox, cow, and horse are supplied to the tanner from the slaughter-houses of this country in a fresh state, soon after the animals are killed. Large quantities are also imported from foreign countries, particularly from La Plata, in South America, where thousands of fine oxen are slaughtered every year for the sake of their hides, horns, and hoofs—the flesh having hitherto been wasted for want of a ready and effectual method of preserving it for exportation to Europe. The hides of these animals are either dried in the sun—as the *charqui*, or jerked beef, is also—or they are salted, and in this state of preservation shipped to the United States of America and Europe.

The tanning materials are the astringent barks of certain trees—more especially the oak—which abound in the chemical principle known as *tannin*, or tannic acid. Sumach is also rich in tannin, but, on account of its high price, is employed for morocco leather only. Whichever bark is employed, it is reduced in bark-mills to a coarse powder, with such precautions as to prevent the dust given off from entering the lungs of the attendant workmen, to whom it is very injurious.

The qualities desired in a good sole-leather are, that it be compact, flexible, and but little absorbent.

To attain these results, the hide or skin, when received by the tanner from the butcher, is freed from all useless portions adhering to it, such as the fat, horns, and hoofs, and washed, to remove the blood and dirt.

The dried hides received from Central and South America are, in the first place, soaked in water, in order to bring them as nearly as possible to the same state of suppleness and distension that fresh or green hides possess.

Salted hides are also put to soak, in order to free them from the salt they contain, which, if allowed to remain, would interfere with the tanning process. Salted hides become soft much quicker than dried hides, as their suppleness is preserved by the salt. This operation is performed in water that has been previously employed for soaking skins in, for it is found that such water, charged with animal matters, acts more quickly and efficaciously than clear water. Most of the tanneries of Paris are situated on the river Bièvre; the skins, fastened to the banks by ropes, are left to soak in this stream, and they become softened very quickly, because the drains from all the tanneries and other factories carry into the Bièvre a large quantity of matters in a state of decomposition.

Upon removal from the water the skins are beaten with an iron bar, in order to remove the creases, and to "break the nerve" of the skin, and render it more supple and easier penetrated by water. The skins are next piled one upon another in large stone vats, where they are submitted during several days, according to their nature, to the action of slaked lime mixed with water into a cream. The lime exercises a peculiar effect upon the skin, rendering the removal of the hair quite easy, but is, in some respects, injurious.

The removal of the hair may be effected by other methods—viz., by a spontaneous fermentation of the skin, by heat artificially applied, and by sour tan liquor.

The method by *natural heat* is that usually adopted with fresh skins. This heat is generated spontaneously when the skins are piled in heaps. The piles must be frequently examined, so as to ascertain the time at which the hair comes off easily when pulled, but not too easily. If the heating be not checked in time—that is to say, if the fermentation be continued too long—the skin is decomposed, and the leather made of it will be found deficient in weight and quality.

At one time, this heating process was effected by the heat of a dung-heap, and worked very well; but there was a difficulty in examining the skins, and ascertaining how far the fermentation had proceeded. A stove-heat obtained by burning spent tan, in which the skins were placed on wooden horses, has been employed; but that process has been improved upon by the steam process invented by M. Delbut, in 1838. The steam is introduced under a false bottom, and penetrates into the chamber by holes made in the upper part. The condensed water flows out at the bottom by suitable apertures.

The fermentation necessary to cause the removal of the hair from the skins may be produced by sour tan-liquor. This method requires a series of vats—from seven to ten—about 5 ft. 8 in. in diameter, and 3 ft. 8 in. in depth. From seven to eight skins, at the most, are put into each vat. The process is conducted methodically—that is, the first vat contains the weakest solution, the second a stronger solution, the last having the strongest of all.

The skins are first placed in the weakest solution, so as to become perfectly soaked. They are lifted out (*handled*) twice every day, and laid on the edge of the vat to drain. At the expiration of an hour they are returned to the same vat, and next day passed to the second vat, where the solution is a degree stronger. This change of vats is renewed until the hair becomes loosened, which in summer time takes place in eight or nine days, and during winter in from ten to twelve days. The temperature causes the skins to swell, and opens the epidermis sufficiently to allow the hair to come off readily.

When the skins are brought to the point at which the hair can be easily removed, they are submitted to the *unhairing* process, which is performed by means of a round knife with two handles, upon a convex wooden bench called a *beam*. The unhairing must be performed upon a *couch* or *layer*; that is, skins must be laid, folded double, upon the beam, so as to form an elastic bottom, upon which the skin to be unhaired is placed.

The implement employed possesses the advantage over the knife in not damaging the skin when it is handled by an unskilful workman. Every care is taken to prevent dirt coming between the knife and the skin, else the bloom would be damaged. Still, when the *unhairing* is difficult, and the hair will not come off, the skin is dusted with sifted ashes, or very fine sand, which facilitates the operation.

The skins are next returned to the vats and washed in clean water, and then worked again on the beam with a circular knife, with which all the flesh and other impurities and useless portions still adhering to the skin are removed. The skins are again returned to the vats, and also washed and worked on the beam with short blunt knives, for the purpose of removing all the lime and water the skin may have imbibed. This labour is very fatiguing: it compels the workman to stoop over the beam, and to spend his days in a very damp place. The quantity of water required has prevented warm water from being employed in these manipulations.

After soaking a few hours, the skins are put into a vat of spent tan, or ooze, in which they swell a little, and next day the bloom is worked with a round knife. If any hairs remain attached to the skin they are removed by hand with a pair of pincers.

The skins being again rinsed, they are put into vats of sour tan-liquor, in order to swell, or *raise* them by acid fermentation. The sour liquor is made with tan from pits in which the skins of a preceding operation have been immersed, and upon which water is poured and left to become acid. The weakest liquor is taken first. There are six or eight vats of liquor, each increasing in strength, then a *new* vat, which contains fresh acid liquor, to which some tanners add a certain quantity of sulphuric acid, the mixture being well stirred.

The first day that the skins are put into the *new* vat they are lifted out twice, and left to drain an hour. On the second day they are lifted out only once. The liquor is carefully stirred before the skins are replaced in it. On the third day the skins are passed into another *new* bath, also filled with fresh acidulated liquor, like the preceding. This is the *new swelling*, or *raising*. The skins are lifted again in the evening, left to drain for an hour, and then returned to the liquor. This operation is repeated during two days more, then the skins are left to repose from four to six days: they are now ready to be tanned. The processes of tanning will next be described.

FLOWERS FOR PERFUMES.

FLOWERS for perfumery purposes are principally grown in the neighbourhood of Grasse, Cannes, and Nice, three towns situated in the South of France, close to each other. The manufacture of perfumery materials forms one of the principal branches of industry in that district, giving employment to upwards of 10,000 people, including many women and children, for whom the work of culling flowers and picking off the stocks is particularly suitable. These flowers are generally grown by small farmers, who contract with the perfumers for their crop, with the exception of orange flowers, which are always sold on the market. The prices flowers realise vary a good deal, according to the abundance of the crop. They average as follows:—Roses, from 4d. to 8d. per lb.; orange flowers, 6d. to 10d.; jasmines, 1s. to 1s. 6d.; violets, 1s. 6d. to 2s. 6d.; tuberose, 1s. 3d. to 2s.; cassie, 2s. to 3s.; jonquils, 1s. to 1s. 6d.

The following are approximate quantities and values of flowers consumed for pecuniary purposes in that locality alone:—Orange flowers, 2,000,000 lb., worth about £50,000; roses, 600,000 lb., £15,000; jasmines, 150,000 lb., £8,000; violets, 60,000 lb., £6,000; cassie, 80,000 lb., £6,000; tuberose, 40,000 lb., £3,000.

The plants from which essential oils are usually made are not cultivated, but grow wild on the mountains; for, as Byron says:—

> "'Tis not the plant upreared in cloth
> Which beauty shows, and sheds perfume;
> The flowers which yield the most of both,
> In Nature's wild luxuriance bloom."

The principal plants from which essential oils are derived are—lavender (*Lavandula vera*), spike (*Lavandula spica*), peppermint (*Mentha piperita*), rosemary (*Rosmarinus officinalis*), thyme (*Thymus vulgaris*), wild thyme (*Thymus serpyllum*), and marjoram (*Origanum majorana*), which are distilled on the spot by means of portable stills. An essential oil is also extracted from geranium (*Pelargonium odoratissimum*), which, from its strong *rosy* flavour, is much prized by perfumers, and the bitter orange leaves yield a powerful essence named *Petit-grain*, which is used in eau-de-Cologne.—*Rimmel on "The Commercial Uses of Flowers."*

Facts and Memoranda.

MORE than 1,500,000 human beings derive their sole support from the culture and manufacture of the fibres spun by the silkworm.

CALIFORNIAN ORES.—Ores are now sent from California and Nevada to Swansea, in Wales, to be smelted. 25 per cent. more silver is extracted from Nevada silver ores at Swansea than would have been extracted in America.

WOOD PAPER.—A fine white paper can be made out of wood. A company has been established at Philadelphia which converts daily twenty tons of wood pulp into a soft white paper. A number of literary and scientific men visited these works recently, and saw a poplar tree on a hill side cut down, and witnessed its conversion into clear, fine paper, all within the space of five hours!

NEW FEATURE IN MUSEUMS.—The Free Museum, Peel Park, Manchester, is to have a permanent gallery of photographic portraits, uniform in style and size, "to be taken from life in the first instance, and printed by an important process, invented and patented by Mr. Swan, of Newcastle, which is claimed to have made photography as permanent and indelible as a printed engraving."

COAL IN WALES.—A provincial paper states that the Welsh coal-field has been tapped at various parts by mines, and there can be no doubt that a layer of first-class steam coal exists there 20 square miles in superficial area, with an average thickness of 30 feet. Every cubic yard of this vast field contains a ton of coals. About 150 million tons have been extracted, and the annual extract at the present time is about eight million tons. At this rate the coal-field will last upwards of 13,000 years. The north of England coal-field, which has been worked for nearly 2,000 years, and shows no signs of exhaustion, is not to be compared with the Welsh field in point of magnitude. The latter has not been known more than thirty years.

WAGES IN LANCASHIRE.—Mr. Baker, inspector of factories, in his last report, remarks that the increase in the wages of cotton workers between the years 1854 and 1860 was greater than at any other period, owing to improvements in machinery enabling the hands to turn out more work. He gives a table, showing the rate of wages in 1850, last year, and three intermediate years.

	1850.		1853.		1854.		1860.		1865.	
	s.	d.	s.	d.	s.	d.	s.	d.	s.	d.
Spinners (men)	20	0	22	0	20	0	27	0	30	0
Carders (men)	20	0	22	0	20	0	28	0	25 to 34	
Grinders (men)	14	0	15	4	14	0	17	0	16	0
Rovers (women)	12	0	13	2	12	0	13	6	15	0
Throstle spinners (girls)	8	9	9	8	8	9	11	9	—	
Weavers	10	0	11	0	10	0	12	0	8	6
Self-actg. minders	—		—		—		22	0	30	0

NITRO-GLYCERINE.—The inventor of the practical adaptation of nitro-glycerine to blasting purposes, Alfred B. Nobel, appeared as a witness in the action at New York against the shippers of the package which exploded at San Francisco. He testified that the preparation will not explode by setting fire to it, by friction, or by concussion, but that it requires 360 degrees of heat in a confined space to explode it. He has been engaged in the manufacture in Germany more than a year. Mr. Nobel accounts for the accident at San Francisco by presuming that the oil leaked into the sawdust packing, and was thus heated to the requisite degree. He refuses to believe that the catastrophe at Aspinwall was caused by nitro-glycerine, saying that had a single case of that substance exploded the ship's bottom would have been blown out, and there would have been no second explosion. The inventor also stated that he was engaged in investigating the effect of the oil when mixed with sawdust, believing that thus a much more dangerous compound was obtained than nitro-glycerine itself.

WORKING MEN IN TOWNS.—It has been said that there is one great advantage which working men obtain by working in large towns, in preference to the rural districts, whether it be in large commercial houses or in great manufacturing establishments. They are directly able to earn much more money; but even this is not the principal advantage which they gain, for they are almost invariably so circumstanced as to get an insight into the modes of acquiring wealth pursued by their employers, and thus acquire an education of immense value. It would be easy to adduce instances without number illustrative of this fact. Of Mr. Rennie it is said that his manufactory "was indeed a school, in which some of the best mechanics of the day received a thorough training in machine work, and many of his workmen, like himself, raised themselves to the rank of employers of skilled labour." The same remark is true of very many other establishments. It is said of the workmen employed by George Stephenson that they acquired a skill and precision in the manufacture of the several parts of the engines made by him, which not only enriched the master, but that his workshops were a school or college, in which the locomotive workmen of the kingdom were trained, and many of the most celebrated engineers of Europe, America, and India acquired their best practical knowledge in his employment

FAMILY LIFE IN THE WORKMAN'S HOME.

RECENT writers have spoken eloquently of the power of the family as a moral regenerator. M. Jules Simon regards it as the bow of promise, which spans for the workman the dark clouds which have gathered over his horizon. M. de Gasparin last year filled two volumes with his own living, penetrating thoughts, as to what the family is, and what it is intended to accomplish. It is an agency for human happiness which dates from Eden itself; when God found for man his help-meet, he constituted the first human family.

But family life has its laws, which cannot be transgressed with impunity. The different lot assigned to the man and the woman, from the very beginning, may be regarded as among the most essential of those laws. The man is to labour in his vocation as a bread-winner—the woman is to labour in her home; his life is to be outward and social—hers private and domestic. We cannot improve upon God's order; we may not violate it: in ordinary circumstances, *family life* flourishes only under these conditions.

It is not the daily toil in the sweat of his brow which threatens the workman's domestic peace; it is that we have taken the key-stone from his arch by tempting his wife away from her proper and natural sphere of domestic labour. Work! who would be without it?—it is the healthy exercise of our faculties, our courage, our perseverance, our enterprise! Let those answer who, having no fixed occupation, have tried to substitute for work a continued round of exciting pleasure. Are they happier than the honest working man, who comes back after his twelve or thirteen hours' labour with his basket of tools slung over his shoulder, and looks in at his own door to see the faces of wife and children brighten up at the sight of his smile and the sound of his voice? Every man, rich or poor, has, or ought to have, his work; the loving intercommunion of members of a family is far more likely to be endangered by idleness than by labour.

And assuredly, in pointing out that the house-mother's sphere of labour lies at home, we have not claimed for her a life of ease! If one woman, during the years in which a young family is increasing around her, contrives, through all her days and hours of weakness and incapacity, to nurse her children, bring them up in good habits, cook, mend, and wash for her husband and the whole family, and keep her house or room in anything like neatness and order—whatever else that woman is, she is not an *idle* woman.—*From "Lending a Hand."*

FRESH AIR!

OR, VICTORIA PARK PRESERVED.

GOOD people all, both great and small,
A bumper, everywhere,
To Parliament fill that threw out the Bill
For robbing poor men of fresh air.
For I own I likes fresh air,
I loves a breath of fresh air;
And dim their eyes whenever they tries
To rob a poor man of fresh air.

Some people thinks gasometer stinks,
Is respiration fair;
But I'll always contend, to my life's end,
That there's nothing to breathe like fresh air.
For I own, &c.

The health of men cyanogen
And hydrogen impair.
Whenever my chest with sitch is opprest,
I wish it was all fresh air.
For I own, &c.

Sulphureous fumes the lungs consumes,
And burns the trees all bare;
But I always find both body and mind
The better for good fresh air.
For I own, &c.

O! 'Tis my delight on a holiday bright
In Victoria Park to fare;
Where Moll and I, with little 'uns by,
Resorts for a breath of fresh air.
For I own, &c.

Moll read the news we was to lose
The good of our walking there;
I could smoke my pipe but not eat my tripe
If the gas-works had poisoned the air.
For I own, &c.

Of all things thirst isn't quite the worst;
There's one that's as hard to bear:
Which is want of breath, being stifled to death,
Like them as is robbed of fresh air.
For I own, &c.

Let companies shape their projects to scraps
Up wealth, and dividends share.
But dim their eyes whenever they tries
To rob a poor man of fresh air.
For I own, &c.—*Punch.*

MONEY PRIZES,

TO BE COMPETED FOR BY

WORKING MEN.

TWENTY PRIZES—TEN of FIVE POUNDS each, and TEN of THREE POUNDS each—are offered by Messrs. Cassell, Petter, and Galpin. One Prize of Five Pounds for the Best Essay, and One Prize of Three Pounds for the Second Best Essay will be given. The list of subjects and the conditions of competition appeared in Nos. 10 and 11 of the Working Man.

We have much pleasure in announcing that the following gentlemen have kindly undertaken the adjudication of the Prizes:—The Right Hon. Lord Houghton; Right Hon. Lord Lyttelton; Right Hon. Lord Talbot de Malahide; Lord Milton, M.P.; Charles Buxton, Esq., M.P.; John Stuart Mill, Esq., M.P.; Rev. Charles Kingsley, M.A.; Rev. F. D. Maurice, M.A.; and the Rev. J. Begg, D.D.

Lambeth and Mr. Doulton.

As the working class increase in knowledge, and aspire to political power, they increase in the liability of responsibility, if we may use so unusual a phrase. The public will expect them to show that they possess political judgment, and look forward to their exercising it. A case in which they may display it has arisen in the affairs of the borough of Lambeth. Mr. Doulton, one of the representatives, has taken a course on the Franchise Bill which has been made the subject of free and somewhat indiscriminating comment. When a public man takes an unexpected line of action he is generally condemned in a ready-made way. The ready-made way may be right in this particular instance, but it should not be adopted without examination. Independence of view is not common, and needs to be encouraged; therefore, when any case of it occurs, public opinion should rather incline towards it, and it should not be hastily subjected to censure. The exercise of independent judgment may be, as we have said, erroneous; but it should not receive censure until it is found to deserve it. Even rightly founded reproof should be arrived at deliberately and pronounced gravely. The fickleness of the multitude is proverbial. Nothing gives more weight to any class, or commands for it more respect, than to find that it reverses its decisions slowly, and is generous and patient in its judgments. Representatives who believe their constituents to be fickle study their caprices instead of their interests, and appeal to their humours rather than to their understanding. We should like to see a popular constituency, like that of Lambeth, act in a manner to raise the character of constituencies in which working men have undoubted influence.

Mr. Doulton takes great interest in preserving the commons for the people—we do not mean the House of Commons, but the commons, sometimes called the Parks of the People. To other social questions he is a friend. We do not say that this alone atones for any great dereliction of political principle; but, if a public servant has some widely-admitted good qualities, that is a reason for well considering whether any fault alleged against him, is such as to warrant the course of superseding him.

Lord Grosvenor's amendment, for which Mr. Doulton voted, and which is the reason of the censure expressed by many upon him, was an amendment calculated to put off and, perhaps, destroy the Franchise Bill. Here arises a question of political morality, to which very little attention is paid. Ought a member of Parliament to vote for a proposition because it is right in itself, or because of the consequences involved in it? If a man votes against a right thing because consequences he disapproves may result, he does evil that good may come. This has always been considered a wrong rule in morals. Again, if he always votes for the right principle, regardless of consequences, he may do great mischief in trying to do great good. He may be an obstructive, and, with the best intention, saddle upon the country sudden and serious evils. He may throw out a good Government and bring in a bad one; he may throw out a Cabinet inclined to peace and bring in one inclined to war. Now, on what principle should a member act? If Mr. Doulton should look only to consequences, then he was wrong in his Grosvenor vote. If he should look only to the intrinsic meaning of the amendment, he might be right. To look to consequences only is expediency, to look to truth only seems the best. There is most independence in this course, but there is also uncertainty of results. Mr. Doulton should explain on which principle he acts. His constituents, before they condemn him, should make up their minds on which principle they should wish him to act, and give him notice of the view they take of his duty.

Apart from consequences following from Lord Grosvenor's amendment, it might be wrong in itself. It may be held that the Franchise Bill was a distinct question; that it was an entire question—a sufficient question—and stood alone; and ought to be treated alone; and that to connect with it another and very different question, was to confuse as well as delay the Franchise Bill. Here Mr. Doulton would be held to have been guilty of an error of judgment by those who took the views last described. For this he might be condemned, but without being dismissed. A meeting of his constituents might consider this question, and agree to mark his act as an error. This would be judicial, it would be fair, it would be a warning, it would be moderate, and honourable to their judgment. For one error a man should hardly be dismissed. This would be a measure so hard that only an infallible member, or one who took care to do nothing, could hope to escape.

A Member of Parliament may have been a long-tried and consistent Reformer like Sir William Hutt. To dismiss such a servant because of one mistake, would have a bad effect on the morality of Members of Parliament. It would not be treating them like gentlemen, but like apprentices. Conservatives have not been better than working men in this. One of their leading journals sarcastically wrote of the Member for Gateshead—

> "Content is found in lowly cell;
> Freedom of mind in prison shut;
> And independence loves to dwell
> (Let Gateshead witness) in a Hutt."

This was treating Sir William Hutt as one who had no right to defer to the wishes of his constituents, on a great question affecting their own interests and hopes, and on which they were the best judges. On national and international questions, and such as affect other parts of the country remote from a constituency, a Member of Parliament, knowing or having access to all the facts of the case, is often a better judge than his constituents. But on questions of personal right, credit, and liberty, the constituent is a better judge than—certainly as good a judge as—the member.

On such a question as that raised in Lambeth, we think Mr. Doulton owed his constituents a grave and explicit explanation of the course he thought it right to take. A member may disappoint his constituents on a vital question, if he gives serious, intelligent, and intelligible reasons for doing so. If he differs earnestly, respectfully, and reluctantly from them, he ought to be borne with, unless he has abandoned altogether those principles which he held when he came before them, and which constituted the reasons why he was chosen. In such a case he is bound to resign.

Our argument is, that constituencies, especially if large and popular ones, should judge with caution, with sense, and with liberality. A member should feel that he is in fair and not capricious hands—that the confidence in him is not lightly given nor lightly withdrawn. We should like to see what is called a "working class" constituency, wiser, graver, juster, more staid in their acts than an ordinary constituency. We wish to see them act without hasty suspicions, or passionate determination. Such conduct would do more than a thousand theoretical arguments to incline Parliament to increase the power in their hands.

At the same time, we would not hand over constituencies to the caprice or irresponsible dictates of members. The doctrine of a member's independence is often carried much too far. Men like Mr. Bernal Osborne, just returned for Nottingham, seem to abuse the right of self-action. He declares he will never give a pledge; and many members who never mean to keep any promise, cover their conduct and evade all responsibility by a show of independence, which affects to regard pledges as improper or degrading. Now, no one expects a member to pledge himself always to be of one opinion upon every question, of which he knows nothing, which he has never studied, and is unaware of what may be said on both sides. But on great public questions, which have been agitated for years, he does know something, he ought to know something, and if he does not he has no business to be a Member of Parliament. None require Mede and Persian pledges, which can never be changed; but explanations of what a man's opinions really are are wanted, and ought to be given, and can be given. A man can tell how long he has held his opinions, why he has held them, and how long he is likely to hold them. Weathercock members, blown about by every ministry, or puffed round by every party that gets in the ascendant, who have one opinion one day and another the next, and who say they will give no pledges because what they really mean is that they have no convictions, and can't afford to keep a conscience—these

are members whose proper place is at the bottom of the very first poll to which they can be brought.

Electrotyping.

ELECTRO-GILDING AND SILVERING.

The Gold Bath.—Gilding can be done either hot or cold; in each case the composition of the bath is the same, only the gilding with a warm bath is generally richer in tone, and may sometimes render *colouring* unnecessary. With a cold bath, necessitated by the difficulty of heating large masses of liquid for the production of bulky articles, *colouring* is always indispensable. Gilding by cold baths has nearly disappeared from workshops where steam is employed.

The baths are formed of double cyanide of gold and potassium. Dissolve 2 oz. of gold in *aqua regia*; evaporate the solution to a syrupy consistence; redissolve it in warm water, and add, little by little, 2½ lb. of cyanide of potassum, previously dissolved in water. This will make about thirteen gallons of bath. It is best not to employ it until it has been boiled several hours. The most suitable temperature for the bath, when in operation, is 160° Fahr.

Immerse in the bath a plate of gold put in communication with the positive pole, and which serves to feed the bath continually. In proportion as the gold is deposited upon the object to be gilt placed at the negative pole, a nearly equal quantity of gold is dissolved at the positive pole, and maintains the bath in the same state of saturation.

By this arrangement the cold baths acquire great durability; it is also applied to warm baths, but they deteriorate very quickly. The cyanide of potassium is destroyed by a prolonged boiling. The electric current is furnished by a Bunsen's battery, the number of cells being regulated by the nature of the article to be gilt.

Before putting the articles into the bath, they are rinsed in alcohol, in order to dissolve the greasy matters by which they are soiled; next into a bath of dilute nitric acid; then into a bath of acid nitrate of mercury, strength 4 per 100; and lastly, rinsed in abundance of water: the articles are then ready to be immersed in the gold bath. The time of the immersion varies according to the thickness to be given to the coating, and is in direct proportion with the weight of gold deposited.

To ascertain the weight of gold deposited, two weighings are necessary; the first, when the articles are about to be put into the bath; the second, upon the gilt and dried articles.

All the metals gild equally well in the above bath, but steel requires a more concentrated solution, or, what is better, a previous coppering in an alkaline bath. Aluminium cannot be gilt directly; it must be coppered also. In this case an acid copper-bath is best for the purpose.

Reserves.—By means of reserves we may obtain various artistic effects, for which taste is the only guide. The most suitable varnish for this kind of work is composed of copal varnish, oil, and chromate of lead. This varnish is applied with a hair pencil to all those parts of the article where it is not wished that the metal should be deposited. When it is allowed to dry properly it is not attacked by acid or alkaline solutions. It is completely dissolved by essence of turpentine or light coal oil.

Green and Red Gilding.—We may obtain green gold and red gold directly by the battery. For green gold a solution of the double cyanide of silver and potassium is added to the gold bath until the desired colour is obtained; then we operate with an anode of gold alloy. In this process, as in all those which have for their aim the deposit of metallic alloys, it is very important to well proportion experimentally the surface of the anode to that of the article to be gilt. To obtain red gold a solution of cyanide of potassium and copper is added to the gold bath. But the result is obtained more easily with the mixture formerly employed by the mercury-gilders, which consisted of 25 parts of acetate of copper, 65 of cream of tartar, and 10 of table salt, applied with a soft brush. The articles are heated over charcoal until the salts assume a brownish colour; they are then cooled in water acidulated with nitric acid.

Upon removal from the gold bath the articles are generally of a tarnished colour, in which state they are unfit for sale. They have, therefore, to undergo several operations with the scratch-brush, and colouring and burnishing.

Polishing.—This operation is performed with a scratch-brush of brass wire, the diameter of which varies according to the delicacy of the article. It is always performed under a liquid—generally liquorice-water—the object of which is to form a light mucilage, which admits of the scratch-brush rubbing the gilt article less roughly.

For smooth surfaces the hand-labour is replaced by the wheel. Upon an axle revolving 600 times a minute a mandrel of copper is mounted, furnished with a brass wire brush; a reservoir above constantly supplies the brush with the mucilaginous liquid, which flows into a lower receptacle. One workman can accomplish as much with the wheel as ten without it.

Colouring is performed by means of a mixture called *or molu*, and composed of 30 parts of alum, 30 of nitrate of potassa, 30 of red ochre, 8 of sulphate of zinc, 1 of common salt, and 1 of sulphate of iron. It is applied with a soft brush. The articles are placed over a clear charcoal fire until the salts, melted and dried, assume a brown aspect; they are then suddenly cooled in nitric acid water containing 3 per 100 of hydrochloric acid; afterwards washed in abundance of water and dried with sawdust.

Burnishing is effected by means of hard stones—agates, hematites—mounted in strong wooden handles, or with tools of highly-polished steel.

Flat Gilding. — Starting with the principle—"As is the surface so is the gilding"—if we can obtain a perfectly *mat* surface before gilding, it is evident that we shall have very little to do in order to retain this aspect after gilding. The result has been obtained by previously depositing a *mat* coating of a less costly metal than gold, the deposit of which can be easily regulated.

Silver and copper equally accomplish this aim. The silvering is performed in baths, which will be described in our next; only the silver bath must not contain more than eight grains of silver per 1,000, and the deposit must be made slowly with a very weak current. The coppering is performed in the usual baths of sulphate of copper, after a first coating given in the alkaline copper bath. The time of immersion and the energy of the pile are conditions which a little practice will soon teach.

The articles being perfectly *mat*, are conveyed to a more dilute gold bath than that prescribed above, which is worked warm. It must not contain more than five grains per 1,000. It is important to continually move the articles about in the bath, and to manœuvre the anode so as to render the colour uniform. Gilding upon copper, less costly than gilding upon silver, is usually of an inferior tone of colour, and more liable to oxidise; so the latter metal is generally preferred.

POLISHING-WHEEL.

The metals deposited under the influence of the electric battery do not always present the same physical characters.

Sometimes the deposit is rough and brittle, at others soft and flexible; sometimes it possesses intermediate qualities, and is as perfect in its physical properties as the best rolled copper; lastly, it may be deposited under the form of a non-adherent crystalline powder.

These different molecular states depend on the relations which must exist among the four following conditions—1st, the proportions of the two electrodes; 2nd, the strength of the solutions; 3rd, the temperature at which the operation is carried on; 4th, the intensity of the pile.

In all cases, it is important that the relative surfaces of the anode and the articles in communication with the negative pole be nearly equal. A positive electrode larger than the negative electrode tends to produce a crystalline deposit, which may extend to the pulverulent state, if the difference in their dimensions is very considerable.

By working with a too concentrated solution,

* Continued from page 309.

the deposit is rough and brittle; increasing the intensity of the battery will restore the deposit to its normal state.

If the bath be too weak, or the temperature be too low, the deposit slackens, and assumes a crystalline appearance, which may be easily made to disappear by raising the temperature, or by diminishing the intensity of the pile. If the temperature be too high, the deposit will become pulverulent. This may be remedied by diminishing the power of the pile employed. The regulation of the intensity of the current is, in most cases, the remedy to apply to the accidents that occur.

Therefore, it is on the perfect equilibrium among these four conditions that the galvanic precipitation of a metal with all its special qualities of ductility and malleability depends. The operator soon acquires the means of working satisfactorily.

In those cases in which a simple cell is employed the success of the operation depends on the relation between the zinc surfaces and the number of articles to be coated. With perfectly saturated solutions, and a weak current, success is certain.

Rambles among Country Clubs.

COMMUNICATED BY THE REV. H. SOLLY.*

"From B—— I went to B——. The Club there occupies two rooms, for which it pays £12 a year rent and taxes. One of the two rooms is used as a reading-room, and the other as a smoking and recreation room. In the latter are a piano, bagatelle-board, and the necessary appliances for the games of chess, draughts, and dominoes. The Club does not possess any skittle-alley, nor yet any kind of recreation ground. Its reading-room is well furnished, and it has a small library. It has no means of accommodating classes. In the winter a social meeting, at which songs, recitations, &c., are given, is held once a week in the reading-room. The number of members is about sixty, paying 2d. per week each, and the Club is not in debt. Its prosperity is due, under Providence, to the unceasing exertions of its secretary, Mr. ——, aided, whenever requisite, by the generous assistance of F. J. ——, Esq.

"My next visit was to D——. Soon after its opening, the D—— Club had nearly 300 members; at the time of my visit there were but about ninety. The average number last winter was 120. Originally the members were all working men; but now they are chiefly tradespeople, clerks, and the better class of apprentices. For some time past the number of working men among the members has been under twenty. The original terms of subscription were 1s. per quarter, or 4d. per month; but last Christmas the terms were raised to 1s. 6d. per quarter, or 6d. per month. The Club pays £16 a year for its premises, which comprise a reading-room, a conversation and smoking-room, a bagatelle-room, and apartments for the housekeeper. The housekeeper, besides being allowed to live rent free, and being supplied with coal and gas, is paid 7s. per week. The Club possesses neither recreation-ground nor bowling-alley. It has two bagatelle-boards, however, and several sets of dominoes, chessmen, &c. &c. There is, also, a good piano. It has no library, and, not possessing any rooms available for the purpose, has not been able to do anything in the way of classes. Last winter something or other in the way of an entertainment was provided for the members once a week; but the committee of the Club seem to feel that they have got almost to the end of their resources in that respect, and strongly urged upon me the desirability of the Union putting itself in a position to *lend* to country Clubs, on moderate terms, magic-lantern slides, *apparatus for the performance of conjuring tricks*, or any other such aids to innocent amusement. They were getting into debt, too, and felt that the Club must die unless something could be done during the coming winter to put new life into it. They had some thought of commencing the winter season (last year they began it with a tea-meeting) with a public meeting at the Corn Exchange, if the Secretary of the Union would go down and attend it. They were also very desirous to receive from the Secretary of the Union all the information and advice he could render with respect to the establishment of *provident societies* in connection with Working Men's Clubs, some of the members of the committee being of opinion that the only hope of the D—— Club lay in the establishment of some kind of *benefit, saving, or loan club* in connection with it. A perhaps larger proportion of the working men of D—— than of most other towns possess 'allotment gardens;' and 'beau shows,' invariably held at public-houses, are very popular among them. This has led the secretary of the D—— Club, Mr. B——, to conceive the idea of endeavouring to attract working men to join it by arranging for an annual horticultural show in the Corn Exchange, *to be exhibited at only by members of the Working Men's Club.* The persons who exhibit at each 'beau show' have to pay something, in order to acquire the right to exhibit; and the money thus paid by all exhibitors is divided, as 'prizes,' among the most successful ones. Prizes would have also to be given to the most successful exhibitors at the show which Mr. B—— proposes; but Mr. B—— believes that he could collect the money for the prizes, so that the subscriptions of all persons who might be induced to join the Club by reason of none but members of the Club being eligible to exhibit at the proposed horticultural show would be available, without deduction, for the purposes of the Club. I must add that I found the committee very much perplexed by the *boy* question. More than half the members of the Club, at the time of my visit, were under nineteen, and a great many were not more than seventeen; and the younger of this section of the members were in the habit of almost monopolising the *games*, so that other members could scarcely ever get a turn at them. In this and other ways the 'boys' had been the means of driving away many older members; and I found the committee divided in opinion as to which course would enable the Club to render most service to the community—that of dismissing the boys, in order to render the Club more attractive to older members; or that of keeping the boys, and so preventing their forming public-house habits, though at the cost of keeping older men away. I shall forward with this a copy of the rules of the D—— Club. At the time of my visit the Club was in debt to the amount of something under £10. Its income was not providing for more than two-thirds of its expenditure, and the committee was getting hopeless of obtaining donations wherewith to meet the other third.

"The worthy secretary of the D—— Club, Mr. B——, was earnestly desirous that I should visit the 'Workman's Hall,' at M—— L——, and was kind enough to drive me over for the purpose. This admirable institution owes its existence to the late Mr. Edward Gaunders, of Bath, who bequeathed to certain trustees £1,000 with which to establish it, and prescribed the plan on which it must be conducted. As certain essential '*club*' elements are thereby denied to it, I need not trouble you with particulars concerning it. I will send with this, however, a printed account of it, which was given to me."

[N.B. I hope to give some interesting particulars shortly of the work this Hall has been doing since it was opened. I heard the other day that every public-house but one had been shut up, in consequence, in the town, but I have as yet no authentic statement.—H. S.]

"The last place at which I called was M——. There I found a Club, which was opened on the 29th of December last year. During its first quarter it averaged 209 members; at the time of my visit it had about 150. The members pay 1s. per quarter, or 4d. per month, or 1d. per week. They possess the most comfortable Club-house I have seen. It is a house belonging to the Marquis of A——, who is the President of the Club, and the Club occupies the whole of it. The Club owes its existence mainly to Dr. F——, of the M—— College, and this gentleman collected about £200 with which to start it, nearly the whole of which sum was spent in adapting and furnishing the Club-house. In consideration of its having spent so much money in improving the premises it occupies, the Club is not to pay rent for them for several years. The premises comprise a reading-room, a recreation-room, a smoking-room, a kitchen, and apartments for the housekeeper. The reading-room is supplied with not fewer than seven daily papers,* and twenty-one weekly and monthly journals, and the games-room with a bagatelle-board, two sets of chessmen with boards, *seven* sets of draughts with boards, five sets of dominoes, and with appliances for several other games, as solitaire, German tactics, &c. &c. The Club also possesses the nucleus of a good library. During the winter it provided for its members a considerable number of admirably-managed and very successful entertainments. It has done nothing yet in the way of classes or lectures, but it contemplates making strenuous efforts in those directions during the coming winter season. Its experience, so far, has been very pleasant and satisfactory, and its prospects are altogether very promising."

* Continued from page 311.

* "These are all *given* to the Club, by members and others, and their only *cost* to the Club is thus 9d. a week for collecting them."

STRIKES AND EMIGRATION.

It is much to be regretted that emigration has been connected with disputes between masters and men as a means of producing an artificial scarcity of labour. Emigration is at the present time a subject of such serious importance to whole classes of labouring men, that it is most desirable they should be allowed to deliberate upon it, having regard only to its independent merits, and without the slightest regard to any temporary derangement of the relations of masters and men in any particular trade. The frequency of strikes of late years in England is one of the circumstances which every right-thinking working man will, no doubt, take into account as one of the disadvantages of his home; and to this extent strikes have a direct and legitimate bearing upon emigration. The first duty of a man who contemplates this most grave resolve a working man can ever make, is dispassionately to view his general position at home, and then to estimate upon trustworthy data his probable position in the place towards which he is directing his inclination. If, upon this, his determination is to emigrate, let him go with a full assurance that he has earned the honour, and deserves to reap the whole reward due to a man who, under circumstances requiring a very high degree of moral courage, was brave enough to do his duty. At a time of conflict, of bitterness and wrath, a man is not in a state of mind to take an unprejudiced view of his normal position. During a trade disagreement a man generally labours under a sense of some wrong which he is powerless to redress, and in angry temper he magnifies the difficulties and diminishes the advantages by which he is surrounded at home; whilst his mind is more than usually open to the exaggerated or perhaps positively false impressions of the condition of things described to him as existing in some happier land far away. This, then, is the time when the working man is least capable of forming a trustworthy judgment upon the momentous question of emigration. Even if left to himself, he would be in danger of rushing upon an uncertain future. He is not, however, even left to himself, for immediately a strike sets in emigration crimps mingle themselves amongst the working classes, and use, in canvassing for emigrants, the ordinary artifices of the recruiting sergeant. These men use the deluded artisans to gain head money from the transport ship owners, or to be played like pawns upon the squares of an allotment map by some Yankee land jobber.

These rash emigrations, in a large proportion of instances, lead to great misery, and, if any are fortunate enough to return from their voluntary exile—and sometimes the stronger members of families do succeed in getting back home—they justify their return by painting in colours too dark the miseries they encountered in their new home. Although such experiences will not prevent emigration, yet they create prejudice against certain localities, and thereby unfairly bias the judgment of those to whom an entire change of the field of labour would be a great and permanent advantage.

What has been already said upon the subject of emigration is only incidental, and collateral to the main argument against its use as a means of affecting the value of labour in any given trade. The fact is, the rules which govern market value are not disturbed in their operation whether attempts are made to alter the relation of supply to demand by one means or another. If a hundred men are withdrawn by emigration, the capital for employing those hundred men will soon be withdrawn also. It is only a question of the transition disturbance whilst the market is righting itself. Practically it does not matter whether by restrictions upon apprenticeship, stint of days' work, or other means, you prevent something coming into the commodity side of the scale, or whether you take something out of it by emigration; the effect in either case is the same, for it is in either case equally easy to take a corresponding portion of the weight out of the other side, and balance the scales. An arbitration would certainly check the operations of your strike-hunting emigration agent.—"*Strikes and Arbitrations*," *by Rupert Kettle.*

Growth of Plants.—M. Duchartre, who has been investigating the rate of growth of plants by day and by night, considers that the greatest increase in length takes place at night. His measurements have been made on the vine, the gladiolus, the strawberry, the hop, and other plants.

Co-operation among the Fisher-folk.

IN TWO PARTS.

PART I.—THE OYSTER-FARMERS.

PERSONS having occasion to visit Canterbury should not fail to extend their tour to Swale Bay, at the mouth of the Thames, and so see Whitstable, which, in the elden time, was the port of the famous ecclesiastical city. The ancient town of Whitstable is interesting as being still, even in this age of rapid change, a fishing-place pure and simple. No gaudy villas or plastered terraces of inconvenient houses have yet been erected for the accommodation of summer visitors. The place still retains its primitive appearance of a long row of cottage-like houses, as also its "fish-like smell." Its old commerce in oysters still forms the staple industry of the place; and it is the mode in which that commerce is carried on that renders Whitstable interesting to persons who study the specialities of labour—for the fisher-people of Whitstable are what may emphatically be called "a peculiar community;" in other words, they carry on their business as oyster-farmers, on the co-operative instead of the competitive principle, and have most successfully done so for a period of more than seventy years.

One has but to peep into the well-filled shell-fish shops of the great metropolis to see that there is a large trade carried on in oysters; but very few of those who indulge in the delicious bivalve know much about the organisation which is constantly at work for their benefit. They have, perhaps, a dim idea that men go out in boats to the deep waters, and shovel the oysters up as they are required for the London market. They are not so curious in their inquiries as to have ever penetrated so far into the county of Kent as Whitstable, nor have they at any time had the happiness to find a cover laid for them at one of the oyster feasts of Colchester. "Let us have street oysters, 'channel roughs,' at four a penny, or 'natives,' fattened out of all flavour, at a shilling the dozen," is about all that oyster-eaters desire; where oysters come from, how they are bred, how they are captured, and what is their natural history, is of no moment, so that the passing desire be satisfied.

The idea of a regularly-worked oyster-farm—a farm with its watery fields, and its produce in different stages of progress, from the tiniest infant oyster up to the marketable animal—does not all at once come home to us; but at Whitstable there is such a farm, and it is about this sea-farm and those who work upon it that we now desire to give a little information.

To those who are versed in natural history there is nothing very astonishing in the idea of an oyster-farm; for the oyster, being, so to speak, a non-progressive animal, is easily dealt with, as, by means of a dredge, it can be brought to the surface of the water for examination, and so can be easily transplanted from place to place. Many persons, no doubt, think that the oyster would grow and multiply as well if it were let alone as it does under cultivation—that Nature is all and all; but to suppose that would be a great mistake. The oyster is rendered doubly, or, indeed, twice doubly valuable by cultivation; and an oyster-farm requires the same care and attention that an agricultural farm requires: there is a time to sow and a time to reap in the liquid water-fields of the sea, as there is on the more substantial fields of the solid earth. The cropping and cultivation of an oyster farm goes on in some of its varied departments all the year round. At one period the brood is sought for and laid down on the beds; at another time the men dredge for the market; and when not employed in either of these operations, they are employed in cleaning the ground and rooting out the enemies of the oyster.

As some of our readers may be aware, the oyster yields an enormous number of young; but it is not known for certain whether each oyster spawns once a year or at periods of a longer interval; and in some years the "spat" perishes, or, at least, never comes to maturity, in consequence of cold or uncongenial weather. A full spatting season—and to obtain a full spat, the weather must be warm and genial—will supply brood for three or four years. Of late years, however, the spatting has been very intermittent; the best falls we have had for some seasons were in 1859—60. If the spat emitted by the oysters belonging to the Whitstable Company were to fall on their own grounds, the co-operators would soon become enormously wealthy; but the spat from the native oysters at Whitstable is usually wafted away by tides or waves to a considerable distance, so that it may fall, perhaps, on what are called "the flats," and the oyster-farmers will have to buy it all, or as much as they can obtain of it, back again, in order to nurse it into edible oysters for the London market. After the spat has had time to form into oysters it is dredged up by dredgers in boats, or gathered by persons who make a business of collecting it on the foreshores when the tide is at ebb, and sold either to the Whitstable farmers or to others who have private beds of oysters. The oysters at this stage are called breed, and in size they range from the circumference of a threepenny piece to a sixpence. As showing the value of oyster cultivation, it may here be stated that in four years a bushel of brood will grow into five bushels of oysters! A great deal of money used to be earned by persons going out to gather these young oysters, as they are always eagerly bought (more especially during recent years, when the spat has been intermittent) by the oyster-farmers, whose business it is to grow them till they become of the requisite size for consumption in the London or other shops. A period of from three to five years is necessary for the full growth of an oyster. Some persons say they can send their oysters to market at the end of about thirty months; but the present writer thinks it would be far better for the grower if oysters were not sent to market till they were fully four years of age.

The extent of ground cultivated by the oyster-farmers of Whitstable is about two square miles, and the beds are constantly covered by the water, except on very extraordinary occasions. A general fishery has existed at Whitstable from time immemorial, but of late years the men have directed their attention solely to the cultivation of oysters. In the year 1793 the Whitstable fishermen purchased the foreshores on which they now reside, as well as the exclusive right of fishing, from the lord of the manor. At the time of their formation into a guild, in the year we have named, the number of members was not more than thirty-six; but at present there are at least 300, besides 108 who are non-effective, widows, &c. They began their labours deeply involved in debt, having had to borrow no less than £30,000 to pay for the ground and stock it with oyster-breed. The company has long since paid off this debt, and two years ago their stock of oysters was valued at nearly half a million sterling. These Whitstable men pay enormous sums every year for brood, and in some seasons they have been able to sell about £100,000 worth of oysters!

The directors, who more immediately carry on the business of growing and selling, are elected by universal suffrage; there is a foreman, an under-foreman, and a treasurer, and these three officers appoint a jury of twelve of the dredgers to aid them in carrying on the business in all its various branches of buying, selling, and cultivating. It is the duty of the officers and their jury to decide how many oysters shall be dredged for the market, in which decision they are, of course, guided by the advices sent from their London salesman. At present any number of oysters could be sold in the London markets; but, of course, in the absence of a plentiful spat, and in the face of an ever-rising market, it is necessary to proceed with caution, and not to send away too much of the stock.

One cannot become a member of the Whitstable Oyster Company except by birth, as only the sons of the dredgermen are eligible. Widows are supported from the funds of the company, and are allowed one-third of the income which is made by the men, and the men of Whitstable earn good and regular wages, and obtain an occasional bonus as well. They have not earned less out of the farm during the last eighteen years than £1 3s. a week, and the bonus, in 1863, was as much as £20. It is thought that the present earnings of the Whitstable men on their own farm will be fully £100 per annum; but, as only a comparatively small portion of the men's time is taken up by the work of the farm, they have many opportunities of adding to their income by gathering brood on the "flats," or going out for whitefish. Upwards of £34,000 has been paid at Whitstable for wages in the course of a year, and all the work required in return from the men may be performed in three hours! The work of dredging for market is, of course, only carried on during those months in which it is legal to dredge, and the "stint" of work appointed for each man does not take more than two hours to perform. In the off season, when the men dredge for what they call the "planting"—*i.e.*, for the purposes of keeping the ground clean, and killing the numerous enemies of the oyster—they generally work about four hours at a stretch. The work performed during the close season is of great value in preventing the accumulation of mud or weeds upon the ground, as these would soon prove as fatal to the oysters as the five-fingers and mussels, which are the greatest enemies of the bivalve. Another operation that is then performed is the classifying and arranging of the stock: the large oysters are set aside on the market-ground, and the smaller ones are relegated back to their watery beds till such time as their beards be grown. The labour on the farm, it will thus be seen, is not by any means oppressive, and the men have ample time to earn extra money by working for themselves, assisted by their families.

As showing the amount of business done by the oyster-farmers of Whitstable, the following figures will be found interesting:—The quantity of brood bought for cultivation, cost, during the last five years, the sum of £80,000, the average price, in consequence of its scarcity, being 12s. per wash. The oysters sold in the same period of time amounted to considerably over a quarter of a million sterling!

There are other oyster companies, both in Kent and Essex, that carry on their business after a similar fashion. There are in all twenty-seven square miles of water devoted to the purposes of oyster-farming at Whitstable and its immediate vicinity: fifteen miles of this is private ground, and the rest is public, except in so far as a portion of it has been ceded by Parliament to a joint-stock company. On these grounds, public and private, upwards of 3,000 men find a means of support for themselves and families, and it is estimated that nearly £200,000 per annum is spent in wages in connection with the Kent oyster-farms. The coast of Essex is equally rich in its private oyster-beds; but, as we have something that is interesting to relate as to the doings of other classes of fishermen, we shall pause for a while.

THE AMALGAMATED SOCIETY OF ENGINEERS.

THE fifteenth annual report of this society consists of 367 closely-printed pages, and almost equals in size one of the ordinary Parliamentary blue-books. Some of the facts made known by the report and the numerous pages of figures are very remarkable. It appears that, during the past year, the Amalgamated Society has added nearly £28,500 to the previous accumulated fund, owing to the reason that during the year trade has been exceedingly good; 3,583 new members have been added, and at the close of December there were, in all, 30,978 members. The accumulated fund of the society at the close of the year amounted to no less than £115,357 13s. 10½d., or £3 14s. 5½d. per member, apart from the arrears, although the expenditure during 1865 was as much as £49,172 6s. 2d. About seventy of the branches have deposited their funds in the Post-Office Savings Banks, amounting to about £24,000, "and I believe," writes the general secretary, "many more will avail themselves of this privilege—a privilege obtained through the kindness of the Chancellor of the Exchequer, Mr. Gladstone, who richly deserves the best thanks of this as well as all similar institutions." During the year £14,070 4s. 9d., or 9s. 1d. per member, has been paid to members out of employment, being £2,355 less than that paid in the previous year. On sick benefit there has been paid £13,785 14s. 9d., or 8s. 1d. per member expended—the two benefits requiring no less a sum than £17,855 19s. 6d. to support them during the year. To superannuated members the sum of £5,184 17s. 4d. has been paid, being £1,282 11s. 9d. more than in the previous year. This difference is caused by the increased benefit now allowed to the members who, through old age or infirmity, are under the necessity of claiming superannuation. This is a most important benefit of the society, and one that cannot be too highly appreciated by the members generally, for it has proved a great solace and relief to many old and deserving members, 260 of whom were in receipt of its benefits at the close of the year. In cases of accident the sum of £1,800 has been expended, being £500 more than the amount paid in 1864. The funeral benefit amounted to £4,887, or £985 in excess of the previous year, so that the sum of £39,728 2s. 10d. has been expended in payment of the five principal benefits—namely, donation to unemployed members, sick, superannuation, accident, and that of funeral, during the year.

The Needlewomen's Institute.

The following account of a visit to this useful institution, situate at 2, Hinde Street, Manchester Square, is extracted from a new and interesting volume, by the author of "Doing and Suffering," &c., entitled "Lending a Hand," of which we intend giving a notice in the next number of our Journal:—

"Our ring is answered by one of the very smallest specimens of 'Buttons' we ever remember to have seen; active as a little sprite, however, and well up to the duties of his calling, which are, at the present moment, to usher us into the presence of Miss Ellen Barlee, whose interesting book, 'Our Homeless Poor,' gave the first impulse to this scheme for the employment of women, and whose untiring exertions have maintained and fostered it, till it has reached its present proportions, and deals with an income of £10,000 a year.

"From Miss Barlee we hear what classes the Institute is intended to benefit—not married women whose husbands are in health and in work, but widows, or wives whose husbands are suffering lengthened illness, and single women. It is her plan to receive *respectable* persons only, and no woman can obtain work who cannot obtain a recommendation from her clergyman or district visitor, or the city missionary of the district, or a subscriber: by this care at the outset, such an honest class of workers has been secured, that out of some 390,000 shirts which have been made by the women, mostly at their own homes, not forty cases of pawning or loss have occurred.

"Miss Barlee's aim has been to secure for the worker the increased pay which ordinarily, in a large contract for work, goes to make the profit of the middleman. She is herself the middlewoman between her *employées* and Government, receiving and becoming responsible for the execution of extensive contract orders, while she pays to the workwoman the highest price consistent with making this part of the operation self-supporting. The advantage to the workwoman will be apparent when we state that, whereas formerly the price paid by contractors to Government shirt-workers was from 3½d. to 4½d. per shirt, Miss Barlee gives 7d. for each shirt, with the additional help of the stitching being done by machinery, which is worth, in the worker's own estimation of time, 2d. per shirt more. A quick worker will make two and a half or three of these shirts a day.

"Our kind conductor took us into her office, a commodious room on the ground floor, answering to the dining-room of an ordinary house, where the indefatigable secretary, Miss St. John, receives ladies who come with orders for work, gets through her share of correspondence aided by a letter copying-press, and presides over a large cupboard full of account-books relating to different departments of the work, which might turn the brain of a less methodical accountant.

"Into these books we were privileged to look: one might be called 'a case-book,' and contained in a fourfold column the names of the women to whom work had been supplied, the names of the parties recommending, the circumstances of each case, and the reason for help being discontinued. No eye could glance down the column which told of the circumstances, without feeling the heart oppressed with its brief record of misery and want, sickness, death, misfortune, grinding poverty. A few words told the tale, and a thick folio volume was rapidly filling with such cases. Surely a blessing must rest on the effort which has searched out this misery, and met it with a fitting remedy! The column which recorded cases of dismissal from employment was almost empty, and for a most satisfactory reason. 'The conduct of the women,' said Miss Barlee, 'is now so uniformly good, that it is not once in the year I have occasion to complain.' Their sense of gratitude to herself was marked by their subscribing together, without her knowledge, to get for her a handsome dressing-case.

"Each woman is paid according to the quantity of work she accomplishes. We opened the wages-book, and taking a page quite at random, noted down the figures it contained, which represent the weekly earnings. They are as under. Only in one case, where the item is £1 1s. 3d., was the amount earned by mother and daughter; in all the rest they are single earnings, and the earnings in the case of in-door workers, of five days in the week, nine hours per day, for on Saturday the institution is closed for cleaning:—

s.	d.	s.	d.	s.	d.	s.	d.	s	d.
7	2	6	11	6	5	7	6	12	6
5	11	4	7	21	3	4	8	10	3
4	11	4	11	6	5	6	10	5	1
4	7	7	8	5	2	9	10	7	10
8	10	6	2	7	1	7	2	6	8

"This will give an idea of the substantial help rendered to these destitute women; about 100 work in the house, the remainder take their work home; this, in the case of widows with little children, is an important advantage.

"Rules for the out and in workers are framed and hung in conspicuous places in the institution; for the out-workers they are as follows:—

"Out-door workers are to arrive at half-past nine a.m. on Tuesdays and on Fridays, keeping regularly to their own day, and are to bring in the full number of shirts they took away.

"No Tuesday-worker will be attended to on a Friday, and no Friday-worker will be attended to on a Tuesday.

"The gate will be locked at half-past two p.m., and no worker admitted after.

"Any worker going in or out of the front door will be fined 3d.

"Any worker detaining her work beyond a fortnight will be fined. In case of illness she is to write to the secretary, and is to return the work, made or unmade.

"Any worker changing her residence is to inform the secretary and the inspectress.

"The work is required to be kept quite clean; any returned soiled, must be paid for by the worker.

"Cheerful obedience to the inspectress's orders strictly enjoined.

"Any worker found guilty of pawning the work would be dismissed from the Society altogether.

"For the in-door worker they are as follows. (We have given these rules in full, as we cannot but hope that this scheme for the employment of needlewomen will be transplanted to many provincial towns):—

"In-door workers are to arrive at five minutes to nine a.m., and remain in the workroom until eight p.m., when a bell will be rung, and the workers are expected to leave quietly and orderly. One hour allowed for dinner, and half an hour for tea.

"At half-past nine the gate is locked, and no one admitted after.

"Any worker going in or out of the front door will be fined 3d.

"Cleanliness and punctual attendance required.

"Workers absenting themselves from the workroom without some valid reason will be fined.

"Every woman to do that portion of work given to her by the matron.

"Industry and cheerful obedience to the matron's orders strictly enjoined.

"Tea and milk will be provided from the society's funds. Workers must bring their own bread, butter, &c.

"One penny in the shilling will be deducted from the payment of in-door workers, towards the expenses of the Society.

"That is to say, for one penny in the shilling deducted from their earnings, Miss Barlee provides them with tea, milk, cotton for their sewing (which is an annual expense to her of from £60 to £70), gaslight, and fires both in the workrooms and kitchen, implying some ten or eleven fires burning all day, and a consumption of about a ton of coals in the week.

"We paid a visit to the kitchen, where the in-workers take their dinner and tea, and thought it most inviting—a large airy room, with clean benches and wooden tables; a glowing fire on one side, where the rasher might be fried, an oven where a meat-pasty might be warmed and made relishing, and the tea-caldron ready for use.

"A short prayer when they first arrive in the morning, gives its tone to the day's industry. On Friday afternoon a short service, from half an hour to an hour in length, is conducted in the large workrooms by a clergyman. Miss Barlee is very glad when London clergymen will volunteer assistance for this little service. It usually remains in the same hands for a month: she can generally ensure to her clerical friends a congregation of about 100 women. She is also glad to provide for the instruction and amusement of the workers through the kind assistance of lady-readers, who read aloud in the workrooms.

"The cutting-out department is a business in itself; it is carried on in a separate room by two men-cutters and one woman-sorter, whose proceedings we watched with no little interest. On cloth, folded so that 120 pieces can be cut at once, an iron plate is laid of the shape and size of the shirt-collar or wristband to be cut, and the sharp blade of the cutter's knife is run five or six times energetically round the edge of the plate, till it has penetrated all the folds, and reached the wooden board on which the cutting is done: it only remains to separate the pieces which the knife has imperfectly reached with a pair of gigantic scissors. Every Government shirt consists of twenty-two pieces, and must go through the processes of cutting, sorting, stitching by machine of collar and wristbands—giving out the shirt to the worker, taking it in, inspecting it (we saw some shirts in the inspector's room rejected and returned for alteration, because one side of the collar was a quarter of an inch higher than the other), folding it, tying the shirts together in bundles of ten, and carting them away to the Government depôts. About 390,000 of these Government shirts have been already executed by the needlewomen of this institution.

"Our next visit was to the storeroom, a gloomy place enough, but important for the wealth of goods stored away there, waiting to be cut out and made up: it frequently contains several thousand pounds worth of material. Our eye fell on masses of a rough sort of rope in hanks. 'What is to be made with this?' we asked. 'Oh, that is only string to tie up the bundles of work.' Two large worn-out cutting-boards, hacked and hewed beyond all further possibility of planing, won our respect in the storeroom: we thought how much hard, honest labour those roughened surfaces represented.

"All that we had seen hitherto was on the basement and first floor; now we proceeded upstairs to the workrooms. The murmur of pleasure from the women, as Miss Barlee entered the room, showed how warmly her labour of love is appreciated. In the first room, not Government shirts, with the coarse, strong work appropriate to them, met our view, but delicate stitching and frilling, which would bear comparison with the performances of first-class sempstresses. We were in the room where orders for baby linen, ladies' under-garments, and *trousseaux* are executed. In a footnote* we give the approximate prices for making such articles—we say *approximate*, because in all cases the woman is paid in this institution *according to the actual amount of work done;* and it is possible to give orders for under-garments, implying an amount of work which will run them up to almost any price. We saw an enchanting baby-frock, which might have made any mother's mouth water—price, three guineas; but then, in addition to expensive embroidery, this little elegancy was decorated with a number of tucks we did not undertake to count, each about half-a-quarter of an inch in depth.

"Our next visit was to the machine-room, where eight sewing-machines keep up a cheerful cackle, and eight young machinists (chiefly children or very young girls) turn off, with rapid movements of hand and foot, the collars and

wristbands for the Government shirts, or any part of ladies' garments where machine work is preferred.

"Up-stairs again—on the next and highest floor occupied by the workwomen—was the inspector's room, flanked on either side by ordinary workrooms. Every garment must be subjected to rigid measuring and overlooking from the inspectress, every button fitted to its respective button-hole, before the work can be passed and paid for. The Government work is inspected by women engaged expressly for that purpose. Indeed, few people would have an idea of the staff required to work the institution effectively. The sum paid weekly in wages to the needlewomen themselves sometimes amounts to £150.

"It is satisfactory to be able to state that all the operations of the Society we have hitherto described, which may be called the *mercantile part, are now self-supporting*, and the charitable aid afforded by the public in the way of subscriptions and donations goes now entirely to the support of the Charity Funds of the Institution.

"The importance of having a Charity Fund at command can, perhaps, only be fully appreciated by those who are daily brought into contact with grinding misery, by a work such as that to which Miss Barlee has devoted herself. To use her own words, she can tell 'of widows with young children struggling with gaunt famine, dividing a penny roll among four children for their entire day's food; of emaciation and pain, unchecked, preparing their victims for our hospitals; of women lying on bare boards during frost and snow, without covering or fire; of children born to deserted wives, without any means to provide for them.'

"For cases such as these, the Charity Fund committed to her for distribution, under the sanction of a Committee, is invaluable. It is dealt out to the very poor and the sick, by grants of coals, grocery—chiefly tea—clothing, sending the sick into the country for change of air, and the purchase of hospital tickets for those who cannot be nursed at home. Grants out of the charity are also sent to all the local clergy who manage branch institutions; as, for instance, at Chelsea, Whitechapel, Southwark, and Camden Town."

Things Talked About.

The annual report of the Postmaster-General has been issued. It is more interesting than pages of statistics usually are, for it shows not only how the population of our country is increasing, but also the great extent to which the people avail themselves of the facilities of communication. It is trite to say that business is facilitated, but family affections and friendships are also strengthened by more frequent letters passing between relatives and friends at a distance. In the year 1864, the average delivery of letters to each person throughout the United Kingdom was 23; this average was raised to 24 in 1865, which slight advance means that there was a delivery of nearly 30,000,000 of letters over the number of the preceding year; but the average varied considerably in different parts of the kingdom. In England and Wales, for instance, the average last year was 28 to each person, an increase of 6½ per cent. So much for letters only. But when we add to the 720,467,007 letters delivered in 1865, 43,569,955 newspapers, and 53,682,811 book packets, we may obtain some faint notion of the work performed by the postmen in the three kingdoms. On the average—we cannot get away from the averages, for they make the matter one of individual interest—the postman knocked at the door of each inhabited house in England and Wales 151 times, or about three times a week. A tolerably large army of intelligent, hard-working, trustworthy men must be engaged in this work; and it is not very satisfactory to know that they are about the worst paid of any of the Government servants. Let us just mention, for the amusement of our young readers, that more than half a million of valentines were posted on or about the 14th of February, 1865.

The same report informs us that, in 1865, there were 611,819 depositors in the Post Office Savings' Banks, and that they held £6,526,400—a tolerably convincing proof, not alone of the prudence, but of the substantial prosperity of the class which furnish the great majority of the investors. If it were possible to ascertain how much more money is invested in other savings' banks, or building and provident societies, and in life assurances, there might be less disposition in some quarters to underestimate the forethought of the working classes, and their substantial interest in the preservation of order.

A short time since, the Home Office addressed circulars to the local authorities of several of our chief towns, making inquiries relative to the nuisance arising from smoke. Various replies to the circular are now made public. We hear of considerable diminution of the nuisance at Stoke-on-Trent, Liverpool, Newcastle-on-Tyne, Birmingham, Huddersfield, Leicester, and Leeds—places famous for the number of chimneys. There is great difficulty in enforcing the law at Sheffield, Derby, and Sunderland; and as to Manchester, the Registrar-General has published a report which is highly interesting, and should call general attention to the injurious effect of the continuance of the nuisance. Mr. Leigh, the registrar of the sub-district of Deansgate, reporting on the first quarter of this present year, says:—"Coal smoke forms a continual dark and dense canopy over the town, and causes a murkiness in the streets from which they are never free. On the finest day the air is darkened by haze, through whose wide extent the prospect seems bounded as by an impenetrable wall. The constant inhalation of these black particles (of which an analysis is given) must be highly irritating to the lungs, and productive in many instances of an amount of inflammation sufficient to induce incipient phthisis or bronchitis, or to determine the recurrence of these where a predisposition exists. A smoky town atmosphere must contain an abnormal amount of carbonic acid, and a distinct amount of sulphuretted hydrogen and of sulphurous acid; and I know of no circumstance more likely to predispose a population for the reception of fever or cholera than the constant inhalation of an atmosphere vitiated by the presence of sulphuretted hydrogen. This gas does exist in the atmosphere of Manchester. From the chimney of a perfect furnace nothing ought to be evolved but invisible carbonic acid, sulphurous acid, and watery vapour; all else means waste of coal and injury to health. . . . Manchester must be regarded in many respects as a model town; but it is one of the least healthy in the kingdom. Children under five years of age contribute half of the total mortality, while in the agricultural districts one-third of the deaths is their proportion. The artisan's wife dies in middle age; and his own career is cut short long before he has reached the seventy years' term allotted to man." Sheffield, as every one knows, is a smokier town than Manchester, and the deaths under five years of age are more numerous. Mr. Leigh slightly overstates the number at Manchester as one-half of all the deaths; but at Sheffield it exceeds the half. That smoke is injurious to vegetation is a familiar fact. Before the Act for the abolition of the smoke nuisance was enforced in London, and the steamers passing up and down the Thames added their clouds to the volumes pouring from the tall chimneys, there were no roses in the Temple Gardens; now, Mr. Broom, the gardener, can show a choice collection of the finest varieties. Flowers and shrubs will not thrive in impure air; and where they suffer, the health of human beings is in peril: a most potent reason for protecting our pleasure-grounds from the invasion of factories and gas-works.

We have bad accounts from Liverpool of the state of business. The prevalence of strikes is seriously embarrassing the employers of labour. In strong confirmation of our remarks last week, as to the effects of the warlike movements on the Continent, we hear that a manufacturer in Silesia (which, if the war breaks out, will be the first battle-field between Austria and Prussia) has sent word to several of his friends connected with the iron trade in England, that his works, which have hitherto employed 15,000 men, are now closed, and that he can send to England any number of experienced and clever artisans, that may be required.

The coalheavers of Birkenhead have insisted upon being paid, on and after the 21st instant, at the rate of 5s. per day, 8s. per night, and at the rate of 8d. per hour for dock work unconnected with the discharge of ballast or the loading of coal.

A strike among the chimney-sweepers would be a serious matter, especially as a new Act of Parliament imposes a fine on the occupant of a house the chimney of which catches fire. Yet such a movement seems to have been imminent. A meeting of the men has been held, at which it was stated that the average rate of wages now paid is 16s. per week, though in some of the best shops 18s. are given to journeymen, and 21s. to foremen. To earn this the men have to work from twelve to eighteen hours a day, commencing at two or three o'clock in the morning. The several speakers agreed that a society ought to be formed, and that none but society men should be allowed to work in the London shops. A resolution to this effect was unanimously passed—the standard of wages be fixed at 25s. a week; and it is said that several of the masters have agreed to the rate.

One very unpleasant result of the recent monetary panic has been made known. By the failure of the English Joint-Stock Bank, a balance of £700 from the entrance-money to the City of London Industrial Exhibition has been lost, and will have to be made good by the guarantors.

The early-closing movement has found support where it was not expected. The principal drapers in the Commercial Road East have resolved to close their shops on Saturdays at seven o'clock—rather a bold move, considering how much marketing is generally done on Saturday nights in this locality.

A Royal Commission will be moved for in the House of Commons to inquire into the probable quantity of coal contained in the coal-fields of Great Britain, and to report on the quantity of such coal which may be reasonably expected to be available for use; whether it is probable that coal exists at workable depths under the Permian, New Red Sandstone, and other superincumbent strata; and whether they would recommend that bore holes should be sunk in any and what localities. The Commission, if appointed, will also be charged to ascertain and report on the quantity of coal at present consumed in the various branches of manufacture, for steam navigation, and for domestic purposes, as well as the quantity exported, and how far and to what extent such consumption and export may be expected to increase; how far the increase of population must necessarily accord with the increased consumption of coal, and the relations which one is likely to bear to the other; and whether there is reason to believe that coal is wasted either by bad working or by carelessness or neglect of proper appliances for its economical consumption, and whether they would recommend legislation with a view to avoid such waste. We hope the Commission will be appointed, as it is most desirable to obtain authentic particulars on the subject. It will, we believe, dispel many delusions.

Co-operative Intelligence.

Settle Co-operative Society.—The twentieth quarterly balance-sheet of this flourishing society has just been issued, and is of an encouraging character. The amount received for goods sold during the quarter is £966 7s. 6½d., and the amount of profit £109 12s. 3d. This latter sum, less £14 6s. 2d. carried over to next quarter's profit account, was apportioned as follows:—To members, a dividend of 2s. 6d. in the pound, and to non-members half that dividend, on the amount of their respective purchases.

Warrington Co-operative Society.—The report just issued for the quarter ending March 31st says that the society continues to prosper, the sales having exceeded those of the last quarter by £129 14s. 10d. After meeting all liabilities, and writing off fixed stock account, £14 8s. 9d., as depreciation, &c., and adding the balance left from last quarter of £5 10s. to the reserve fund, increasing it to £23 1s. 9½d., they recommend a dividend of 1s. 4d. in the pound out of the profits for the quarter, carrying a small balance to reserve of £2 18s. 6½d.

Kilnhurst.—At the recent opening of the new and commodious stores in connection with the Co-operative Society at Kilnhurst, the secretary read an elaborate report, giving the origin and history of the society, in which it was stated that during the first quarter of the society's existence, in 1860, it sold goods to the amount of £129 9s. 2d. During the quarter just ending the sum had swelled to £851 5s. 9d., thus showing a great increase in the amount of business transacted. With regard to the new stores, they were erected at the cost of about £1,000.

General Information.

CLUBS AND INSTITUTES.

Metropolitan District Association of Working Men's Clubs and Institutes.—The adjourned meeting of Delegates of the London Clubs, announced in a former number of the Working Man to be held at the office of the Parent Society, 150, Strand, took place on Monday evening, the 14th inst., when about twenty persons, consisting of representatives of Clubs and of the Council of the Union, assembled. In the absence of A. H. Layard, Esq., M.P., who was detained in the House of Commons, Hodgson Pratt, Esq., was called to the chair, and opened the proceedings by reading a draft of the proposed rules and constitution for the District Association. Considerable discussion took place as to the name of the society, in which delegates from the St. James's and Soho, Kentish Town, Child's Hill, Clerkenwell, and other Clubs, as well as Mr. Solly and Mr. Pocklington took part. It was ultimately agreed to adopt the title at the head of this notice. Various other resolutions were come to, and it was finally resolved to print and circulate the constitution and plans of the Association among the Metropolitan Club Committees. It is confidently hoped that great benefits will accrue to all the Clubs which join the Association, further particulars with regard to which will be given in a subsequent number.

Halstead, Essex.—A public meeting to promote the welfare of the newly-formed Club and Institute in this industrious little manufacturing town was held on Tuesday evening, the 15th inst. R. E. Greenwood, Esq. (Manager of the London and County Bank), was called to the chair, and the Rev. H. Solly delivered an address, after which Mr. Collins, on behalf of the committee of the Club, and Mr. Ready, its secretary, moved and seconded a resolution pledging the meeting to support the society, which was carried unanimously amid applause. It was stated that the committee had obtained convenient premises, which they invited working men to come and see for themselves. About fifty members

had already enrolled themselves, and there was every prospect of a useful and prosperous existence for the Club. Mr. Courtauld's large silk-mills employ many hundred hands, and there is also a considerable number of other operatives. The Rev. Mr. Robertson moved and Mr. Simons (engineer) seconded a vote of thanks to Mr. Solly, which was carried with acclamation. Wm. Davison, Esq., manager of the silk-mills, who was on the platform, takes a warm interest in the prosperity of the club, but it is managed entirely by the working men themselves.

Hyde, Cheshire.—A Working Men's Club has recently been opened here. It originated in the following way:—The Rev. Charles Beard, B.A., inserted a letter in the local paper, stating that if the working men of Hyde would form a club, the funds necessary to furnish it with every convenience would be found by a gentleman whom he was not allowed to name. A number of working men took it up, and convened a public meeting, which was well attended. At that meeting a provisional committee was formed to make the necessary arrangements. They, fortunately, obtained a building which had been built for a public-house, and made it suitable for their purpose. It contains a large game-room, a reading-room, a smoking-room, a class-room, and a committee-room, besides rooms for the steward. The game-room is supplied with cards, draughts, dominoes, and chess. A bagatelle-board will be ready in a week or two.

Correspondence.

**** We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* Working Man, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*

We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

CO-OPERATION IN EAST LONDON.

To the Editor of the Working Man.

Sir,—As your paper is especially intended for working men, it may not be uninteresting for them to hear something about Co-operation. Monopoly is a curse, and has blighted many a fair prospect. Co-operation is the only effectual remedy for the great evil, and, rightly carried out, must have the desired effect. Four years ago, a few working men began the Victoria Equitable Provident and Industrial Co-operative Society, at 7, Preston Terrace, Green Street, Bethnal Green, N.E.—a very humble neighbourhood. They were few and poor; and after they had done their best, all they had to go to market with was 25s.—yes, £1 5s. With this they started, in a small room belonging to a well-disposed man, of whom they are now renting part of some premises which are used as a store and collarage. We believe in realities, not show and outsides. "Onward!" is our motto, but "steady progress" our aim. We have gone on step by step. We paid in our fourth year for goods, £1,936 19s. 3½d., upon which we realised a profit of £127 17s. 3½d. We have paid on the average on members' purchases, for the year ending March 3rd, 1866, 1s. 5d. in the pound, after all expenses were paid. We seem, after all, to be very small as a society. Our present number of members is only 150, all working men. What has been done by this society may be done anywhere, for in the neighbourhood we have had a great deal of competition, and, I think, sometimes unfair competition. We ask no credit, neither do we give any: our business transactions are for ready money. Our downfall has been predicted often. As to our perpetuity, I have no doubt similar societies around us have made a greater show than we have made, but, like some badly steered vessel, have become wrecks. We have had contrary winds and tides to sail against, but we are still seaworthy. The essentials to success in Co-operation are a good working committee, an honest storekeeper, an experienced secretary, and a judicious purchaser. These are just as necessary as a pilot to a ship. Our committee meet weekly to transact business and to enrol members. One of the secrets of our success has been the keeping down of expenses. If this brief statement should meet the eye of any who have not tried Co-operation, and happen to be near to us, let them give us a call, and I have no doubt they will be thoroughly satisfied, as our goods are neither dressed up nor adulterated.—Yours,

A Friend of the Working Classes.

April 23rd, 1866.

RAILWAY SERVANTS.

To the Editor of the Working Man.

Sir,—In reply to the letter of your correspondent, "A Traveller, Rugby," in the Working Man, will you kindly allow an old railway servant to make a few remarks? Your correspondent says that in the course of his travels he has often heard complaints from railway servants, porters, and platelayers as to their long hours of duty and little pay. I have no doubt he has, and am much obliged to him for calling your attention to the fact, as in so doing he has, thanks to your paper, opened a channel through which railway servants may now make their grievances known to the public, who hitherto have looked upon them as a well-to-do and well-cared-for body of men. But this is not so—far from it—as I think I can very readily show; and, in order so to do, will first commence with porters, who are paid at the rate of 17s. 6d. per week of seven days—for, as you are doubtless aware, they have to work on Sundays, for which they get nothing extra, so that their actual pay is 2s. 6d. per day, which is the same as, if not less than, is paid to a bricklayer's Irish labourer. But this is not all. The latter, if he works an hour or two over what is called a day, is paid for it. Not so the railway porter, who very frequently works fourteen or fifteen, but gets nothing for it. And here I would say, it is in consequence of the Company having refused to pay the men their overtime which causes them to feel so dissatisfied; and the late strike on the Lancashire and Yorkshire Railway was the result of that Company compelling their men to work overtime and refusing to pay them for it. Surely, sir, this is a piece of injustice—to compel a man to work, and then refuse to pay him. Where is the Englishman who will submit to it? Surely, sir, to be compelled to work on the Sabbath is hard enough to endure. Nearly all other classes of British workmen can go home on a Saturday night, and look forward to the coming Sabbath as a day when his toil and labour shall cease, and when he can for once in the week enjoy the comforts and quiet of home, with the opportunity of worshipping that God who, in his all-seeing wisdom and providence, ordered this periodical rest. Not so the railway workman. He must be at his post. The same daily routine awaits him, with but little prospect of a quiet hour or two to devote to his Bible, or any other good book, should he feel ever so inclined to read one.

And now, sir, a word for the poor platelayers, and I have done for the present. They, as a rule, hail from the agricultural districts, under the impression, like many more, that once upon the railway their fortune is made; but some find, to their sorrow, they have jumped out of the frying-pan into the fire. Their average pay, which in this district they receive fortnightly, is 15s. per week. Certainly, if called upon to work on the Sabbath, they are paid extra for it; but surely, sir, 15s. per week is too little for men holding situations of great danger and responsibility, as they do, for we have seen the most disastrous sacrifices of life and property the result of carelessness on the part of platelayers: but can it be wondered at when Railway Companies pay them so badly?

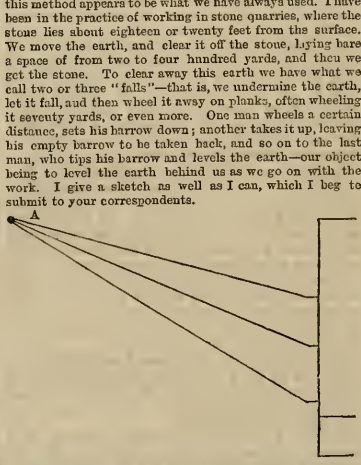
I could say very much more, but am afraid to trespass too far on your space for correspondence; but if you will kindly give this a place in your paper, you will confer a great favour on, yours very respectfully,

An Old Railway Servant.

LESSONS IN MECHANICS.

To the Editor of the Working Man.

Sir,—In No. 12 of the Working Man, Professor Haughton speaks of a method of shifting earth which he describes as being the most wasteful method that could be adopted, and this method appears to be what we have always used. I have been in the practice of working in stone quarries, where the stone lies about eighteen or twenty feet from the surface. We move the earth, and clear it off the stone, lying bare a space of from two to four hundred yards, and then we get the stone. To clear away this earth we have what we call two or three "falls"—that is, we undermine the earth, let it fall, and then wheel it away on planks, often wheeling it seventy yards, or even more. One man wheels a certain distance, sets his barrow down; another takes it up, leaving his empty barrow to be taken back, and so on to the last man, who tips his barrow and levels the earth—our object being to level the earth behind us as we go on with the work. I give a sketch as well as I can, which I beg to submit to your correspondents.



Wheeling here is very hard work indeed, particularly from the last fall, and we should be grateful to any one who can point out a better method of doing it, also what machinery would be required, and about the cost, as this with us is a material point. The first and second falls are wheeled away on planks supported by upright poles—what we call "hollow runs"—and to unpractised hands is dangerous. The last is wheeled on planks laid on the ground.—Yours, &c., A Working Man.

[In reply to the foregoing letter, Professor Haughton states: "I cannot understand why the point *A* is so high, unless there be special circumstances in the case, as in all quarries that I am acquainted with the bearing can readily be tipped into some lower ground, often in the older parts of the quarry. The lift from the lowest run is very heavy, but without seeing the ground it would be impossible to suggest a remedy. If the "box-lift" could be applied, it would save the unnecessary carrying of barrows and men to and fro."]

TO CORRESPONDENTS.

A Workman from the Banks of the Isis, S. G., Work-a-Day, and others.—We do not intend to resume the discussion on the Educational Franchise, enough having been already stated on both sides of the question.

An Intending Competitor.—The Essays will be adjudicated upon according to their literary merits. The manner in which the subjects should be treated is optional with the writers.

Student.—On the authority of Prof. H. D. Rogers, the Illinois coal field is stated to contain 1,277,500,000,000 tons. The Pennsylvania coal field contains 316,400,000,000 tons. All the coal fields of North America, 4,000,000,000,000 tons. The coal fields of Great Britain contain 190,000,000,000 tons. The Illinois coal fields, then, contain four times as much coal as those of Pennsylvania; nearly one-third as much as all those of North America; and over six times as much as all the coal fields of Great Britain.

Apprentice.—Indentures do not usually contain a clause that the apprentice shall not receive any wages during absence through illness. As it was so in your case however, you must, of course, abide by the agreement. Overtime was expressly contemplated and arranged for in your indenture; and you must, therefore, comply with the master's request to work overtime, provided such extra work is not of unreasonable amount, and beyond your health and strength.

Dublin.—The Prize Essay competition is not confined to England, but is open to the whole of the United Kingdom.

The Permissive Bill.—We have received several communications on this subject, but their great length forbids our inserting them.

W. Wills.—Thanks for your letter. The subject is under consideration.

Inquirer.—The chronograph, which has now come to be regarded as the great authority in all matters where it is essential to obtain the rate of speed with perfect accuracy, consists of an ordinary quick train lever movement, on a scale sufficiently large to carry the hands for an eight-inch dial, and with the addition of a long seconds hand, which traverses the dial, instead of being, as usual, just above the figure VI. The peculiarity of the chronograph consists in this seconds hand and the mechanism connected with it. The hand itself is double, or formed of two distinct hands, one lying over the other. The lower one, at its extreme end, is furnished with a small cup or reservoir, with a minute orifice at the bottom. The corresponding extremity of the upper hand is bent over, so as to rest exactly over this puncture, and the reservoir, having been filled with ink of a thickness between ordinary writing fluid and printer's ink, the chronograph is ready for action. The operator, who holds tightly grasped in his hand a stout string connected with the mechanism peculiar to this instrument, keeps a steady look-out for the fall of the starter's flag. Simultaneously, therefore, with the start of the race, the string he holds is pulled by him, and at the same moment the upper hand dips down through the reservoir in the lower, and leaves a little dot or speck of ink upon the dial. This is repeated as the horses pass the winning-post, so that a lasting and indisputable record is afforded by the dots on the dial of the time—exact to the tenth of a second—which is occupied in running the race.

Shirley Brooks.—1. The diameter of the completed Atlantic cable is 1¼ inches: it was covered outside with wire. 2. The mother's refusal in no way weakens her claim.

J. Sondy.—We cannot obtain the information you desire, except by the loss of half a day's time.

J. R. Hitchen.—Thoroughly scour the utensils, finishing with a solution composed of 1 lb. of chloride of zinc, and 13½ oz. of sal ammoniac dissolved in 3 quarts of water, more or less. Melt in an iron crucible (with a flux composed of 1 oz. of borax and 2¾ oz. of powdered glass) 5½ lb. of tin, 5 oz. of iron turnings or wire heated red hot, and 6 oz. of pure nickel, stirring with an iron rod until thoroughly incorporated. This is poured into the utensil, and a uniform surface secured by the application of the soldering iron when necessary. For ordinary purposes an alloy of tin with from one-tenth to one-fourth its weight of lead will answer.

Jolly Blacksmith.—In the cases you mention, the blowpipe is substituted for the furnace.

Acton, W.—The drying oils are linseed, hempseed, and walnut. In *drying*, as it is called, or more properly, oxidising, they become converted into varnishes.

Mechanician.—It is very difficult to ascertain if a foreign invention has been patented in England, as the patents are seldom taken out in the inventor's name, but in that of the agent's. The inventor's address is, Paris Plaisance, 6, Rue Lebouis, Paris.

S. N.—Part of the National Debt consists of annuities, payable for terms of years, to the amount of £1,358,431. Among them are annuities amounting to £585,740, which will expire in April next; annuities amounting to £680,341, which will expire in April, 1885; and the Red Sea Telegraph Company's annuity of £36,000, expiring in 1908. Some annuities have much longer to run; the annuitant is probably not yet born who will receive the £9 9s. 6d. which the State has undertaken to pay to somebody on the 5th of April, 1953.

Vulcan.—Prof. Hodgkinson has shown that strains, however feeble, if long applied, produced some permanent elongation or contraction in bars of iron.

Paperlap.—The preamble of what is known as the "Permissive Bill" sets forth that "Whereas the common sale of intoxicating liquors is a fruitful source of crime, immorality, pauperism, disease, insanity, and premature death, whereby not only the individuals who give way to drinking habits are plunged into misery, but grievous wrong is done to the persons and property of Her Majesty's subjects at large, and the public rates and taxes are greatly augmented; and whereas it is right and expedient to confer upon the ratepayers of cities, boroughs, parishes, and townships, the power to prohibit such common sale as aforesaid.—Be it therefore enacted," &c. The Bill itself provides that, on application of any district, the votes of the ratepayers shall be taken as to the propriety of adopting the provisions of the Act; but that a majority of at least two-thirds of the votes taken shall be necessary in order to decide that question in the affirmative.

The Planet Permanent Building AND INVESTMENT SOCIETY,

Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and all further information may be had of EDMUND W. RICHARDSON, Secretary.

Offices—39, City Road, London, E.C. [4

W. H. ROBINSON, Secretary. [6

Gathered from the Waters.

For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1857, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the Shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,600 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C. [26

THE UPPER AND MIDDLE SCHOOLS,

PECKHAM, LONDON, S.E.

(PRIVATE.)

CONDUCTED BY JOHN YEATS, LL.D., &c.

Pupils enter the Upper School on attaining their Fourteenth Year, or on proving themselves able to do the work of the Higher Classes. The Terms in both Schools are moderate, and inclusive of Books, Stationery, and other charges, which often make the real very different from the apparent cost of Education.

Every Boy is, as far as possible, well grounded in English, French, and German, made to write a hand fit for business, and trained to be quick at accounts. The Continental Languages are taught by Native Masters, and spoken by them to the Pupils. Eminent special Teachers attend for Science and particular purposes. There are periodical Examinations, when suitable rewards are offered. Holidays are short, and the four divisions of the School year are equal. The Premises are large, the Playground spacious, and the General Accommodation superior. Peckham Rye Common is available for Cricket, Football, &c.

N.B.—As a rule, Pupils are not received or retained after the completion of their sixteenth year.

A Prospectus, and Report of Examiners on every Pupil in the Schools, may be had on application; also Testimonials from Lord Brougham and other eminent men.

TO THE MEMBERS OF COMMERCIAL HOUSES.

Gentlemen,

Employers frequently complain of the increased difficulty there is in finding youths who have been so brought up as to be useful in business. This may arise from the requirements of commerce being greater than formerly, or from the inadequacy of the provision made to meet those requirements—or perhaps from a union of the two causes.

Instead of spending years in a workshop or a warehouse, and then going into "the office," as was customary when apprenticeships were more in vogue, a youth now tries to save time to himself and trouble to his employers by remaining longer at school; but he also hopes that his services will sooner become valuable, and a salary be sooner obtained. Of course, he is liable to disappointment, and his friends to loss; yet neither Parents nor Employers can justly infer, as some have attempted to do, that instruction is nearly useless, and schooling unprofitable: rather should both correct mistakes made in the kind of information that has been sought, or the range to which it has been limited. The best educated youths are sure to be preferred, ultimately: competition is their security.

Similar complaints were heard long ago upon the Continent; hence the establishment of places like the public Trade School of Leipsic. Having witnessed the working of that Institution, and kindred ones, during a residence of several years abroad, I opened a Private School in 1852 at Peckham, near London, "for first-class business pursuits." Besides instruction in our mother tongue, in writing and accounts, and more than common attention to modern languages, *Object Lessons* are given here by Chemists, Geologists, Botanists, and others, on the nature and use of many raw materials;* *Historical Lessons* on the origin and progress of particular branches of national industry; with *Special Lessons* on some of the applications of science, on remarkable inventions, on trade marts and trade routes—on *Real Knowledge*, in short, of interest to the young, and valuable in a counting-house, though seldom obtained beforehand.

Habits of order, punctuality, and dispatch are carefully encouraged, or, if necessary, enforced.

The School has been so far successful that for seven years past there have never been in it on an average fewer than 150 boys, day pupils and boarders—last year there were 200. Among them have been Dutch, French, German, Spanish, Italian, North and South American, East and West Indian, African, and Australian boys, and some from nearly all parts of the United Kingdom.

The pupils are classified, according to age and capacity, into three distinct departments—the Preparatory, the Middle, and the Upper. Sons of the opulent, from this latter, have been sent by their relatives into large establishments, where they have uniformly given satisfaction; but others, equally well educated, have had to wait for employment, through want of necessary introductions.

On behalf of such youths, and for the convenience of employers also, allow me to ask the favour of an inspection of the School. The visits of strangers, particularly of foreigners, are always welcome.

In May, 1863, one certificate of honour and two of merit were given to my Pupils at the Evening Classes, King's College, for a knowledge of the principles of commerce. The highest distinctions for Drawings and Models have been awarded to Students of Art whose training began here.

I have the honour to be, Gentlemen, faithfully yours,

JOHN YEATS, LL.D.

Peckham, London, S.E.

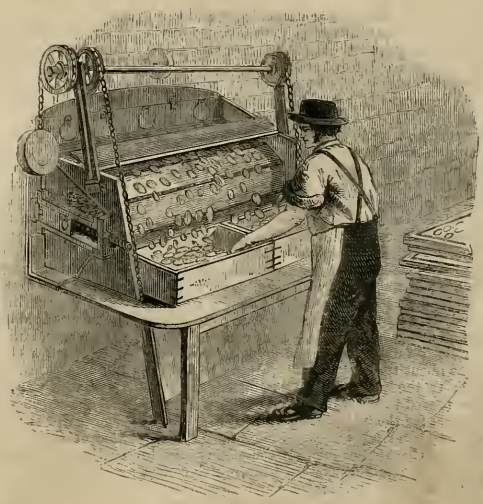
MACHINE FOR CUTTING BISCUITS.

MIXING MACHINE.



TRAVELLING OVEN DISCHARGING BISCUITS.

Biscuit-making at Reading.

Few people have an idea of the extent to which biscuit-making is carried on in the pleasant town of Reading, or dream of the elaborate machinery and number of people employed in the production of those delicate little cates so familiar to the palates of all.

By permission of Messrs. Huntley and Palmer, we are enabled this week to give sketches and descriptions of the manufacture, as practised in their establishment. Upon entering the vast factory (which covers about two acres of ground), one of the first matters to arrest attention is the number of glittering machines at work in all directions; another, the exceeding cleanliness of the entire place, and of the multitude of people—men and boys—employed therein. The workmen look respectable, healthy, and wholesome; and the scene presents a striking contrast, if general report be true, to the bread-bakeries of the metropolis. At no stage of the manufacture does the material employed look other than sweet and tempting, and it is touched by the hands as little as possible—machinery being employed whenever practicable. All flour, wherever procured, is carefully re-dressed in the factory, the butter re-washed, and every precaution taken to ensure the most perfect condition of the various materials which enter into the composition of the different kinds of biscuit.

When these preliminary operations are concluded, a just proportion of each ingredient required for the immediate purpose is weighed and taken to the mixing-pans. The pan shown in our engraving is of iron, circular, and revolves horizontally. Inside this, an upright, heavy, polished iron roller revolves; and a blade of iron, fixed to a movable bar which runs over the pan, assists also in the mixing. The butter, eggs, &c., are conveyed to the man at the mixer, who pours them into the pan, and then, from a long bag or hopper hanging from the ceiling, he shakes out the proper quantity of flour, which is weighed and passed in from a room overhead. In a very short space of time the contents are kneaded by the action of the pan and heavy roller into a stiff paste. In one pan Queen's biscuits are being mixed, at another place macaroons, at a third gingerbread-nuts, and so on. Golden syrup is extensively used in the preparation of paste for gingerbread-nuts; and this, like all the other materials, is carefully prepared beforehand and strained through wire-gauze.

In addition to the mixing-*pans*, mixing-*drums* are used. These are large, cylindrical, drum-like machines of iron, fitted inside with sharp-edged revolving iron arms, which, when set in motion, quickly knead together the paste, and, by their peculiar action when the "drum" is opened, turn out all the dough in lumps into a pan placed for its reception.

From the mixing-pan or drum the thoroughly-mixed paste is taken in great lumps to the "rollers," who pass it between a couple of polished iron rolls, from which it emerges in the form of a thick, long, and immense pie-crust. This is folded into a mass about eight inches thick, and re-passed several times between the rolls; then cut up into large pieces, placed in a wooden trough or pan, and taken to another and closer fitting pair, through which it is repeatedly passed, preparatory to undergoing the operation of the cutting or stamping machine.

Attention to our large illustration will facilitate the reader's comprehension of the action of one kind of cutting-machine (the cylinder) used in the establishment under our notice. A man standing at the end of a very long machine, has the paste brought to him rolled out to a certain extent—say an inch in thickness. Just before him are a pair of polished steel rolls, between which he places one edge of the dough, which is immediately drawn in, and the whole piece drawn through and made thinner. As it passes through the rolls it falls upon an endless band of strong canvas about two feet in width, which brings the dough to the place whence it started, and it is again passed through and rolled out to the proper thickness for the intended biscuit. When passing along the band for the last time, the end of the now long sheet of exquisitely compounded paste is lifted upon another endless band, which carries it away along the machine—past a man who stands to take care that the unbroken sheet (twenty to thirty feet in length) is travelling properly—and between another pair of rolls in front of the machine, one of which has a great number of little cutters upon its surface. At one side, standing in a hole in the floor, will be seen a boy, who is occupied in placing shallow iron pans upon another band, which carries them under the cutting-cylinder, where the biscuits, now cut into the required shape, fall by an orderly arrangement into the passing pans, and are carried to the front; whilst the spare paste, perforated like a piece of delicate network, is carried backward along the middle of the machine to a proper receptacle, and taken thence to be re-moulded. As the laden pans come to the front, they are lifted away and carried to a table, where they are carefully looked over, and all imperfect ones thrown aside.

The trough seen immediately in the foreground is for the reception of those biscuits which are cut from the ends of the long sheet, and do not fall into the pans, or for any which may have fallen over the sides, &c. These are taken away, and made up again into the lump, and those in the pans are now ready for baking.

There is another machine employed here, by which the biscuits are *stamped* out of the sheet, instead of cut by the cylinder. In this the dough is carried forward by a similar arrangement of endless bands, and pressed under a stamp working up and down perpendicularly, and having upon its under-face a series of cutters. We were shown a pair of miniature rolls, about four inches in diameter and a few inches in length, which were, probably, the originators of all the elaborate cutting-machinery now used in biscuit factories. This little apparatus, which could be carried away in one hand, is still in use, and was employed, when we saw it, in the making of "Long Jamaica." The upper roll has the name "Huntley" upon it, and the lower one is grooved. Long strips of dough are passed between these, receiving, in passing, the shape and ornamentation required, and the strips are then cut up with a knife, and the separated biscuits placed in a tray.

For certain kinds of biscuits, the paste, after being mixed, is not rolled into sheets. In making "Queen's," for instance, the composition is brought to the workman in a mass, and he then proceeds to mould them in a very simple manner. A slightly-flattened cylinder lies upon the table before him, hollow, open at one end, and at the other perforated with a number of small holes. The mixture is placed inside by the open end, and forced through the holes at the other, in long, jagged, snake-like lengths, which are afterwards cut up by boys, twisted into various shapes, and placed on tins. The little fellows who twist up these ornamental biscuits are paid by piece-work.

"Macaroons" are made in a somewhat similar way. Men fill little tin cylinders, about nine inches long, with material, then insert a plug of wood at one end, and force out the paste through a hole at the other, and cut off the bits with a knife. These bits fall upon wafer-paper in trays, boys place on the almonds, and they are ready for the oven.

"Cracknels" are brought from the cutting-machine, and thrown into a large pan filled with water, kept continually at a steady boil by means of steam, then fished out with a wire ladle, placed in cold water, afterwards dried on cloths, placed on tins, and baked.

"Ginger-wafers" are rolled out very thinly by hand. So thin, indeed, is the paste, and so exquisitely fine the texture, that manuscript can be distinctly read through it.

The baking-ovens are from sixteen to forty feet in length, of various kinds, and heated underneath, to avoid dust. The one we have selected for illustration is what is termed a "travelling-oven," the floor of which is composed of iron plates jointed together, and forming an endless band, which passes over rollers at each end. This band is continually in motion, and the biscuits being placed in the mouth of the oven, are steadily carried onward, thoroughly baked during the passage, and discharged at the other end into wooden trays or boxes, as shown in our sketch. In some cases they pass through upon the iron trays, which are lifted out upon their arrival at the discharging aperture. The speed at which they travel is regulated according to the thickness of the material, heat of the oven, and the particular shade of colour required. Some of the very thin wafer biscuits pass through in about five minutes, whilst other kinds vary from that time to a quarter of an hour.

After being baked, they are taken in boxes, by means of a "lift," to an upper room—each box containing a tin label, placed there by the baker, to denote the particular oven from which the biscuits are brought; next, weighed and sorted. Every biscuit which has become either spoiled or burnt, is picked out and thrown aside, to be afterwards broken and sold at a reduced price, and no damaged ones are allowed to leave the establishment in a whole state. When sorted, they are placed in store casks, with an accompanying ticket, which denotes the date, thus preventing the possibility of any stale goods being unwittingly sent out.

We next go into a series of rooms where numbers of people are continually employed in packing the tin cases so well known to every one. Thousands of tins are piled about, and at various tables the process of packing is neatly carried on. Into the "best mixed" tins as many as eighteen sorts are placed, each kind carefully proportioned, and the "dessert" tins contain seventeen varieties. Those packages intended for exportation are soldered up.

To show the amount of business transacted, we may state that there are anything but insignificant carpenters', coopers', blacksmiths', and fitters' shops attached to the factory, and devoted to its sole use. Altogether, the firm employs over 800 people upon the premises, whose comfort and improvement are by no means lost sight of. They have, attached to the establishment, a free library, a reading-room (provided with a variety of papers, a piano, &c.), to which all are admitted, if over sixteen years of age, upon payment of one penny per week; and at certain seasons some very pleasant *soirées* are got up by the members. There are also a dinner-room, a play-ground for the boys, and a sick-fund, managed upon most equitable principles.

The members of the firm are proud of their men, and speak of them as being sober, intelligent, and thrifty—a credit to their class.

Saturday Evening in Victoria Park.

Living as I do in another quarter of suburban London, and seldom having occasion to visit the East End, it is not surprising that I should have shared the ignorance so prevalent among many of the peculiarities of this lately much-talked-of locality. Of course, I knew generally that about twenty-two or twenty-three years ago a large tract of land was laid out as a park; that some old houses were cleared away to make approaches; that there was a sheet of water, and that Miss Burdett Coutts had given a sum of money to erect a drinking-fountain. Altogether I had a vague impression that the park was a large place where the East End and the East End's wives and families enjoyed themselves; and when a friend suggested one fine Saturday afternoon that we should go and have a look at the park, I assented, under the impression that I should witness scenes bearing some resemblance to those I had seen when Greenwich Fair was in all its glory, or at Battersea Fields, before that choice locality was made respectable.

"I don't suppose," I said, "I shall see anything particularly novel. Everybody knows all about low life now-a-days. Casual wards, and Ratcliffe Highway, and Petticoat Lane, and Ragamuffin Alley (that's the name, isn't it?), and everything of that sort has been almost done to death by this time. I know all about the sixteen people who lived in one room, and the German sugar-bakers in Whitechapel, and the thieves' kitchens, and the sailors' amusements in the Highway, and the Chinese opium-eaters, and Bluegate Fields, and the slop tailors and shirt-makers, and, in fact, I am altogether—thanks to special reporters, and graphic writers, and 'Readings by Moonlight,' and amateur paupers and detectives—'up' to the East End. But, however, let us go to Victoria Park by all means. The day is fine, and I have nothing particular to do, and may as well see donkey-riding, and three sticks a penny, and kiss in the ring, and costermongers dancing polkas with costermongeresses, and drunken dock-labourers fighting or setting their bull-terriers to fight, as do anything else; for that is about what we shall see, I suppose, isn't it?"

"I suppose so," said my companion. "Some fellows talk about flower-beds, and shrubs, and

winding paths, and all that sort of thing, and say the people go there by thousands to enjoy themselves, and are clean and well dressed, and behave like ladies and gentlemen; that no damage is done; that there is no coarseness or impropriety of conduct, and that, in fact, if you were to go to sleep all the way there, you might wake up and think you were in the Horticultural Society's Gardens at South Kensington or the Regent's Park, or any other respectable place; but that must be nonsense, you know."

"Of course it must," I said, as we stepped into the railway station at Fenchurch Street. "The idea's absurd. I dare say the East-Enders are a good sort of people in their way—rough diamonds, perhaps, but I should think the roughness must be something remarkable. We won't go first class; the second class will give us a better opportunity of witnessing the manners and customs of the East-Enders. Two returns to Victoria Park, if you please."

Very crowded and very dingy is the Fenchurch Street station of the London and Blackwall Railway. There are numerous platforms, and when the train arrives the passengers jump out at one side to make room for others for the return journey, who crowd in from the other platform. The carriages are never empty. One of the first ideas which struck me was, that there appeared to be among the officials of the railway several individuals possessing extraordinary taste in dress and remarkable musical powers. They had black faces and horsehair wigs, battered white hats and red striped trousers, and shirt collars a foot square seemed to be popular, and the banjo, accordion, concertina, and "eddicated bellows" generally, favourite instruments. One of these strange personages stepped lightly into the compartment where we were seated, and immediately began to sing something about a "corn-brake," and "marching on for Uncle Sam." My fellow-passengers appeared to be pleased with the performance, and grinned expressively when the nigger announced that the song was "number two in the collection, and the next one is anoder." I had anticipated as much, and did my best to be highly amused; and certainly the song, which appeared to consist of a short yell and the repetition of the word "tapioca," was, all things considered, quite as funny as I could reasonably expect.

"Not a bad idea," suggested my companion, "and other companies might take the hint. We might as well listen to nigger vocalists, when we are kept for half an hour at a time waiting at junctions, as to the whistle of engines, and the amiable conversation of guards and porters."

"Pass round the saucer, if you please, gentlemen," said the vocalist insinuatingly—he called his old hat a saucer—and then we found that he was not employed by the railway company at all, but was one of many, "plain and coloured," who ride up and down the line all day, and make a tolerably good living from the halfpence subscribed.

"East End all over," said my friend. "Catch them standing that sort of thing on the Great Western!"

In about a quarter of an hour we had reached Victoria Park station; and in another minute or two were in the park itself. Now, what *did* we see there? I will make a clean breast of it, and —West-Ender and "swell" as I am—will tell you that I was altogether wrong; that the park is a charming spot; that the visitors behaved exactly like ladies and gentlemen; and that I never saw so much real, healthy, honest, decorous enjoyment in my life as I did in the two hours we were strolling about in the park. Young and old were enjoying themselves thoroughly. The children were running about, and the merry laughter which accompanied their games was as musical as the songs of the birds which every now and then burst out from the plantations. There is a noble piece of water, with the depth marked, so as to ensure the safety of the bathers; and a whole fleet of model yachts, some of them eight or nine feet high, with polished hulls and scrupulously accurate rigging, were afloat, carried by the gentle currents of the lake, and dipping their slender masts to the light breezes that swept across the park, laden with the scent of the gay flowers and lilac blossoms bordering the water. How the children watched the white sails and the flowing pendants; and how knowingly the yacht-owners criticised the rig and the gaff-topsails of the rival cutters!

Winding paths, made beautiful by shrubs and many-coloured flowers, lead from the lake to the open park. There is the drinking fountain given by Miss Coutts—a noble erection, by far the most tasteful the metropolis can boast. There, too, are wide lawns, where the children play, while their parents sit in gossiping groups; and in the less crowded parts the football flies, chased by the active throngs of players; and kites of all shapes and sizes are overhead. Farther on is the cricket ground, where not only the East-Enders proper, but hundreds of young men engaged in the City houses, find scope enough for exercise. There are red caps and blue caps, and flannel trousers, and leggings; and loud cries of "Now, then, run!" and "Thank you!" resound. Balls speed past us on the ground, pursued by light-footed long-fields, or spin over our heads, directed with sure aim to the wickets. There are cricketers of all degrees; mighty batters and bowlers, and juvenile aspirants to cricketing fame. But the best thing of all is, that everybody seems quite happy. And when, on the verge of the park, we reach, guided by volleys and rising smoke, the spot where the 2nd Tower Hamlets Rifle Corps are going through their drill, we feel that England ought to be proud of the rising manhood of the country, and that means of obtaining fresh air and exercise are essential to its proper development.

Before we passed the lodge, we took a last look at the scene we were quitting. The sun was setting brilliantly, touching the picturesque massed foliage with gold. The old tower of Hackney Church looked venerable in the rich light of the dying day. Far away were the echoes of the great city; and before us the sward was dotted with a thousand animated figures, giving the crowning charm—that of vigorous life—to the animated scene.

The Foresters.

"Every man for every man—himself included."

Forestry! Odd Fellowship! Here are two grand institutions, vying with each other for the best of all pre-eminence—the practice of the most intelligent philanthropy, concord, and benevolence —to secure the greatest happiness of the greatest number—in a word, the universal benefit of mankind. They are both of similar import in the vast and universal want of poor human nature—good-fellowship; the "shoulder to shoulder" without which man is but a poor worm, to be trampled under foot, or to be devoured up by the prey-birds of want and poverty.

We must be grateful and acknowledge that much has been done of late years to improve the condition of the working classes, and the working man of the present generation enjoys many advantages that were far beyond the reach of his less fortunate brethren of former times. Just let us consider. The *tommy-shop* system of robbery has been abolished, and the payment of workmen's wages in public-houses rendered illegal.

Government enactments and inspections have compelled those who employ men in dangerous occupations to take proper precautions for insuring the safety of those employed, and the law now provides against the over-working of children of tender years.

Mechanics' and other institutions of a similar nature have been established; beautiful parks have been thrown open to the city-pent communities, and a variety of other means have been taken with the view of elevating the intellectual faculties and social position of the working man.

He has now an advocate of his rights—his honest and honourable claims—and, moreover, the record, the *monument* of his national *productiveness and skill*—we mean his *journal*—ever ready to give him a helping hand if he needs it, and ever watchful of his interests.

All these magnificent results are an honour to the age we live in, and in accordance with the general advance and progress of humanity as ordained by Providence.

But another striking fact arrests our attention, as still more emphatically demonstrating the advance—the development of our common human nature. It is this: the working man has begun to assert himself—to rise in the might of his own moral and intellectual powers above the grovelling and groping thing of former days, and to stand forth an embodiment of the moral of the fable, "If thou wouldst have me aid thee, aid thyself; put thy shoulder to the wheel."

Yes! A wise legislature has suppressed many of the abuses to which the working classes were formerly subjected. It is well! Private philanthropy and public benevolence have striven, and with great success, to improve their mental and physical condition. Again, it is well! It is "good!" But now the working classes are fully and wisely convinced that it is principally to *themselves* that they must trust if they wish permanently to rise in the social scale, or to be prepared—as far as their circumstances make it possible—to meet those fluctuations in the affairs of our common humanity, against which no human foresight can always forefend us. Hence Forestry.

Friendly societies—the distinguishing feature of modern times—form a subject of the highest interest in the study of the social state. They commend themselves equally to the professional statesman or politician, and to the philosopher who seeks, by his theories, to ameliorate the condition of mankind, whilst the object of the former may be only "to make ends meet" in the governmental point of view, or with respect to the tenure of office. More than *five millions* of the working and middle classes of this country subscribe to a fund for mutual support during the unproductive days of illness, old age, or when out of work. In other words, probably more than one-half of the adult male population has, by thrift and slight personal self-denial, secured itself from the doom of the pauper or the inmate of the workhouse and union. Five millions, at least, of our countrymen have thus combined for mutual assistance in the event of sickness, calamity, and death. It is this genuine appeal to *principle* that we want for the regeneration of society and the safety of nations, instead of regiments of soldiers and multitudes of policemen. Man is not necessarily the brute which we must infer him to be from the frightful shackles and penalties which have been invented and deemed indispensable to keep him in social order and constitutional subjection. There is *mind* in him, which can look forward; there is *heart* in him, that can feel a generous impulse when duly roused; there is in him a *conscience*, which discriminates between good and evil; there is, finally, a strong instinct of upright *self-interest*, to which we rarely appeal in vain, if we are sincere, honest, and honourable in our proposals.

Such, we take it, must be the cause of the wonderful expansion of Forestry, the nature and rules of which we propose to consider in their general working and application.

It appears from existing records that the Order of Foresters was founded at Knaresborough Castle, October 29th, 1745, under the title of "Royal Foresters," by which name it continued to be called until, at a grand convention of delegates held at Rochdale, in August, 1834, it was changed, and is now known as the *Ancient Order of Foresters*.

Steadily advancing in its mission of good, the Order may well appeal to its increasing numbers as a proof of its universal appreciation. In 1845 the number of districts or branches of the Order was 146; last year it was 225; each succeeding year since 1845, showing either a permanence or that gradual increase which is the best security for permanence, because it shows no factitious excitement, which commonly evaporates as quickly as it arises.

In the same period the number of Courts, or divisions, of the Order, has increased from 1,456 to 3,493, the average number of members in each Court having also increased in the same period from 45 to 86. In 1853 the number of honorary members was 1,090; in 1865 it was 5,886; finally, the number of financial members, or such as receive aid from the Order, was, in 1845, only 65,909, whereas last year it was 301,077—considerably over a quarter of a million of men; and striking as is this great strength of the Order, it becomes still more significant from the fact that its increase last year was no less than 23,331.

These astonishing figures tell of good management, and speak plainly of reciprocal advantages secured by this institution in its mission of good to mankind; for the Order of Foresters is established not only in the United Kingdom, but in the colonies—New South Wales, New Zealand, South Africa, South Australia, Tasmania, Victoria, America, and the West-Indies.

In order adequately to account for this great accomplishment in all its bearings, we must con-

sider a few points of which we are daily reminded. A counterpoise is needed, in a well-regulated community, against the undue influence of wealth or mere money. Then, if wealth be made a tyranny, let every man secure himself from its undue influence and oppression by providing for himself in all the contingencies of life, by some such combination as we are now considering. Money can be effectively fought by money only; and the small but real "independence" of the working man may, together with his industry and skill, ultimately alter for the better the relations between the employer and employed throughout society; and these friendly societies, properly organised and properly supported, will be the means of bringing about this desirable consummation. And what will be—what is already the grand result of this mighty cause in operation? Why, the great interest or stake in the country which the working man possesses, concerning which the Chancellor of the Exchequer, in a recent debate, spoke in terms which leave us nothing to add, excepting to quote the *facts and figures* of another speaker, Mr. Layard, who stated that the society called the London Unity had £200,000 sterling of property, and 200,000 members; the Manchester Unity Independent Order of Odd Fellows had £3,000,000 sterling of property, and 387,990 members; and the Foresters had nearly a *million sterling* of property, and 301,000 members, at the commencement of the present year.

These facts and figures indicate the existence of a mighty power in the working classes, and it only remains for a wise legislature to direct that power, and the intelligence and true respectability by which it is accompanied, to the welfare of the state and country.

Henceforth the voice of the working classes must be listened to; their vote must be taken on every great national question. The best effect of their immense influence on public questions has been recently demonstrated, as admitted by the Government, through Mr. Layard, in Parliament—"All the working classes of the country, with the exception of those of Liverpool, supported the Government in their determination not to go to war with the United States."

POETRY AND THE WORKING MAN.

By poetry, we do not mean, simply, verse or rhyme. In a hundred thousand verses there might be not one thought of poetry. Neither does poetry mean something which is fanciful and unreal. By poetry we mean invisible truth, as distinct from that which is visible. Not *every* invisible truth; not, for example, the invisible truths which are perceivable by the understanding, as mathematics, but the invisible realities which are recognised by the imagination. We will take an illustration. You look at this England, intersected with its railways, and say it is becoming a dull, prosaic thing. The sentimentalist will tell you the railway has broken up all the poetry of the scene, because it has run through our pleasure grounds, sadly cut up our old retreats and solitudes, and destroyed all classical associations. So it may have done. It has destroyed that which was associated with the poetry of the past; but it has left us the real poetry of the present. Let men look upon that railroad, and one will see nothing but the machine that conveys the travellers to their destination. This is a truth, but only a visible one. The engineer comes and sees in it another class of truths. It suggests to his mind the idea of broad and narrow gauge; he talks of gradients, &c. Another truth: that which is appreciable by the understanding. Then let the poet come, with that eye of his "glancing from heaven to earth, from earth to heaven," and his imagination creates another class of truths; the suggested meaning of it to him is the triumph of mind over matter, the gradual annihilation of time and space. He sees in these railroads stretched throughout the country the approaching times of peace and human union; and so he bursts out into his high prophetic song of the time—

"When the war drum throbs no more, and the battle flags are furled,
In the parliament of man, the federation of the world."

All this is truth; neither seen, nor reasoned truth, but truth to the imagination; truth just as real in its way as the others are in theirs. And this is poetry. For this reason is poetry a thing needful for the working man. His whole life, if he could be taught to feel it, is full of deep, true poetry. The poet teaches him by suggestive inspiration the hidden meaning of common things, transfiguring life, as it were, by shedding a glory on it; and if you will force the poor man to see nothing but the wretched reality that is around him, if you will not let his mind be enlightened by the invisible truth of things, if you will not let him learn from the master-thinkers of the past how, in his work, in his smoky cabin, in his home affections, there is a deep significance concealed, connecting him, when he once has felt it, with the highest truths of the invisible world, you condemn the worker to a desolate lot indeed.—*Robertson's Lectures.*

*Why are not Working Men's Clubs and Institutes more Successful?**

The following correspondence between Mr. B——, honorary treasurer of the F—— Working Men's Club and Institute, and the Rev. H. Solly, will be found interesting to members and promoters of these useful institutions:—

"Working Men's Club, F——,
10th May, 1866.

"Dear Sir,—At a recent meeting of our committee, I was requested to ask your advice, with a view to the amendment of our position. I enclose you what papers I can, to show you our former condition as compared to what we are now. Our members are now only fifty, and they do not all seem to appreciate the value of the Club.

"Of course the subscriptions will not pay expenses, and honorary members tire of supporting an institution for which the working men care so little. We get very few artisans; there are three builders' establishments, one cabinet maker, two printers, one coachmaker, and one painter, employing on an average eight or ten hands, of whom we have scarcely one on our books. But perhaps our principal difficulty is, that the vicar is not with us, and he, of course, influences many of the men.

"Can you, from these few rough notes, form any idea as to our best course, and will you kindly advise us, if you can?

"Apologising for giving you so much trouble, I am, sir, yours faithfully, E. B——."

"May 15, 1866.

"My dear Sir,—Having carefully considered your letter, let me first express earnest sympathy with yourself and the other friends, both working men and gentlemen, who are striving to keep up the Working Men's Club in your town.

"Secondly, let me draw your attention to your sixth rule, 'That any working man or mechanic (not under sixteen years of age) may become a member of the Club,' &c. Now, as I am glad to see by your report that you take in the Working Man, you must have noticed all that has lately been said there upon the admission of youths to these Clubs. Hence, you can be at no loss to understand one of the principal causes of your want of greater success in drawing young men to your Club. You had better get the age for admission raised, as soon as possible, to twenty-two or twenty-three, so as to have it, practically, at least up to twenty-one—but twenty-five would be better still—unless yourself and friends think you can do more good by turning it completely into a Youths' Club and Institute, or unless you can adopt some of the plans mentioned in my papers in the Working Man for providing separate accommodation for the youths.

"Thirdly, In working these Clubs, we must always remember that there are two forces required for their successful management. 1. The energy and interest of the working men themselves, as the rank and file of the army. 2. The zeal and co-operation of persons in a higher class as leaders or helpers, when and where they are wanted. Neither, as a general rule, has proved to be efficient without the other.

"1. To secure the interest of working men in a Club, the first step is usually a public meeting. If you have tried this, or cannot get speakers likely to rouse the working classes, the next, and far more efficient step in any case, is for those men who do care for the Club to talk about it to those who do not—to do this not merely once or twice, but repeatedly, whenever an opportunity offers, again and again, until at last the right moment comes, and a man's friend or shopmate agrees to join the Club for a time, 'just to see how he likes it.' Personal influence, in short, is the great secret of success in this Club movement. Nothing can supply its place for any permanent result.

"But wise or injudicious rules and arrangements, of course, may greatly help or mar that influence: *e. g.*, a rule allowing a member to bring a friend two or three times without payment is of great use; while penny admissions for a single night are generally mischievous, as destroying the Club feeling, and sense of Club privilege. This, also, I adverted to in two or three of the papers in the Working Man (Nos. 8 and 12).

"To draw the attention of the operatives of the town to the advantages of your Club, you would probably do well to circulate a few hundreds of the enclosed paper, 'A Few Words to Working Men about Social Clubs and Institutes,' accompanied by a short statement of what advantages your own Club offers, with the rate of subscription, &c.

"If you could get up an exhibition, bazaar, out-door fête, &c.—anything to draw general attention to the Club—it would, of course, be a considerable help. The great difficulty you and all supporters of these Clubs have to contend against is the apathy of the working men, and the clinging love many of them have for the publican's fire-side. Whatever will rouse their interest and gain their attention, break in upon their habitual routine, and stupid animal indifference, is of much value.

"But especially the working men who have risen above that low, grovelling condition themselves, must make their comrades understand that at the club they can be just as much their own masters, just as independent, and free and easy, as at the public-house, subject only to their own rules and good feeling, even as in a public-house they must be subject to the landlord and public opinion. I often think of that man's remark, quoted elsewhere: 'We have masters, my lord, all day long, and we don't want 'em at night.'

"2. The co-operation of gentlemen in securing the success of the Club is fully advocated in the enclosed paper—'Working Men need and welcome Help from gentlemen,' &c. If you ask men to give up the excitement of tippling and low conversation, you *must* substitute other and better excitement. Persons who can talk in a sociable and interesting way, who can sing, read, and recite, show microscope, telescope, air-pump, describe the human hand and horse's hoof, &c., or bring diagrams, maps, and engravings, may do much to help less educated and privileged folk to enjoy very pleasant evenings without fuddling. In the same way out-door games and athletic sports sometimes receive great stimulus from the participation in them to a moderate extent of genial gentle-folks.

"Query.—Have you availed yourselves of all these modes of making your Club flourish? Above all, have you and your fellow self-sacrificing workers tried to make the working men, generally, enter into the spirit of brotherly kindness and unselfish labour for the good of those working with them in the shop or the field? There is no hope nor help for any Club, except so far as the members will care for one another, and not merely for themselves. There are two or three other points I ought to mention, but am much pressed for time now, and will write further in a day or two. Let me hear from you again, and believe me, with sincere good wishes, very truly yours, Henry Solly."

"150, Strand, W.C., May 18, 1866.

"Dear Sir,—I now add one or two remarks which I had not time to make in my last letter.

"First, with regard to the unfortunate circumstance of your not having the vicar with you. This is, undoubtedly, much to be regretted, both for the sake of his own usefulness and for that of your Club; but if you and your friends will work on in faith and patience, you will, I trust, be able to show him, six months hence, by actual facts, the great good the Club is doing to his parishioners, and then, we would hope, he may become its cordial friend. I have hitherto had no more valuable and friendly supporters among any class than among the clergy of the Church of England.

"Secondly, I see by the report of our visitor last autumn, that out of your six rooms you appropriate three to your housekeeper. This is a large deduction from your working power. It is generally considered that one bedroom and a sort of bar-parlour is all that should be reserved exclusively for the housekeeper or steward. A man and his wife without family would find this quite sufficient, because they are occupied in attending to the members during the evening, and can use the Club coffee-room, if they want more space, during the day. By your present arrangements

* Continued from page 330.

you get no class-rooms, and, as I have often urged in the Working Man and elsewhere, a Club cannot long be maintained unless there is something of an educational character connected with it. Even the recreation department cannot be properly kept up without it. For instance, unless there is an elocution class there will probably be a deficiency in new recitations for the weekly sing-song or 'free-and-easy;' old pieces will be recited or read till the members are tired of them. More than one such Entertainment has died out from this cause, thereby seriously injuring the Club. The same applies to a singing-class; and with regard to the need generally of making the Club more than a mere recreation-shop, and of attaching men to it by higher and stronger ties, let me ask you to refer to the account you will find in the Working Man of my visit to Bolton (No. 12, March 24th). A discussion-class or meeting, again, I have always advocated as of immense value, if well managed, and kept free from theological controversy and party bitterness.

"For the summer months, note what is said in the Working Man for May 19th, at West Bromwich. Can you not get up a weekly meeting for athletic sports, preparatory to a regular festival, and collect money for prizes?

"Finally, if you think that a visit from me would be of any value, I dare say the Council would pay the travelling expenses, for yours was the first Club we established, and we have always felt a special interest in it. —I am, dear sir, very truly yours, Henry Solly."

THE RESOURCES OF BRITISH COLUMBIA.

The special correspondent of the *Toronto Globe* writes as follows: —"In my last I promised some further reasons why these colonies must inevitably take high rank among the colonies of Britain as soon as they are known and understood. I propose now to take a look at the possibility of the future. In my last I briefly described our varied and vast resources, waiting for the hand of man to take and use them. There is, however, one important condition of a people's growth and greatness about which I said nothing; but as it is one which always exerts a most potent influence on the character and prosperity of any people, it must not be overlooked in any estimate of the merits of our country. I refer to our climate. The southern parts of Vancouver's Island and British Columbia are truly healthy and pleasant countries to live in. Cariboo, and the upper country generally, is probably as cold in winter as Canada, but the district from Vancouver's Island to the western foot of the Rocky Mountains, including Victoria, New Westminster, the lower valley and delta of the Frazer, and the southern inland part of British Columbia, has the best climate, beyond all comparison, to be found in British America—alike free from those extremes of cold and heat which give all your eastern people a moderate foretaste of purgatory twice a year. Not so warm as to enervate, nor so cold as to cramp, it is the best climate I have ever known to work with comfort in. Like the English climate, it is wet in winter, and mud and rain are always disagreeable; but I have seen roses in bloom in the open garden on Christmas Day, and pansies, daisies, and mignonette in flower in January. Gardening generally commences in February. The spring is a long season, not short and sudden, as with you; but this gives the farmer plenty of time for his spring work. The temperature is so uniform that, although I have lived here nearly four years, there has not been a night that I have not needed blankets for covering. Thus we have that kind of a climate in which a man may spend the utmost of his strength without exhaustion, and in which sleep exerts its perfect restorative power. It is a climate most favourable to the complete activity of man. In an economical point of view this is an immense advantage. It does not count for much yet, because none of us are yet fairly to work; but when our hills and valleys, our towns and rivers, shall hum with industry, then this five or ten per cent. advantage which our climate will give us will tell vastly on the total results. Moreover, there are good and reasonable grounds for believing that this superior climate will act favourably on the general *physique* of the people that shall be born and brought up here; and to men who contemplate finding a new home, and who think they detect in the length and lankiness of the Yankee or Australian a degeneracy from those 'whose limbs were made in England,' it is, in all seriousness, a subject worthy of grave consideration. I have been thus particular about the climate for a reason. Short-sighted people, who think themselves practical, give to climate a very small degree of consideration, compared with the attention they bestow upon the present chances a country offers for making money. But, in view of our relations to the rest of British America, and to the Pacific Ocean, the question of climate rises to great importance. These colonies are the western 'hand,' as the Maritime Provinces are the eastern 'hand,' of our British American empire. At present its hands are the hands of an infant, but the time will come when they will possess the strength of maturity, and when their western hand will, I hope, have acquired the superior power of the 'right hand.'"

DRINKING-FOUNTAIN IN PICCADILLY.

Drinking-Fountains.

Now that the hot summer weather is fairly setting in, the utility of the numerous drinking-fountains established in different parts of the metropolis becomes strikingly evident. The accompanying illustration represents a well-known fountain at Hyde Park Corner. In a future number we intend giving some account of the drinking-fountain movement.

Busts of American Inventors.—The United States Commissioner of Patents has invited individuals throughout the country to send to the Patent Office busts of authors and inventors, and of all men who were celebrated for mechanical skill and ingenuity. The Commissioner promises to assign appropriate positions in the Museum, but he has only room for 200 busts. The somewhat similar collection at the Patent Office Museum at South Kensington, commenced some years ago by Mr. Woodcroft, contains about 250 portraits, busts, and medallions of celebrated inventors and discoverers.

A Bored Prince.

Conventionalism is not without advantages. It represents an established order of social procedure into which men fall by habit, who have not reflection enough to fall into it by force of sense. Still the thing comes to be overdone when it is rigidly levied upon those whose sense enables them to see a better course open, and who have judgment enough to take it of their own accord. A very notable instance has just occurred in what is called "high life." The Prince of Wales lately attended the Royal Academy dinner. The speeches were dull, not to say prosy. The new president, Sir Francis Grant, talked long, and not in a very happy manner. Every year, as most of our readers may know, the Royal Academicians give a grand dinner, all among their pictures, before the rooms are opened to the public. On these occasions, the most eminent men of the nation are usually present —prelates, princes, noblemen, and statesmen—and they usually make good speeches. Last year Earl Derby made a great speech. This year nobody made a good speech, and Sir Francis Grant made a great many very bad ones. He talked more than all the guests put together. The late president, Sir Charles Eastlake, was a man of cultivated taste, and knew what to say and when to stop. It was proposed to make Mr. William Boxall president, one of the greatest of our portrait painters. He is said to possess the graceful faculty of being able to entertain with pertinence and brevity a high and critical assembly, such as always meets at a Royal Academy dinner. Sir Francis Grant appears not to have this rare attainment. He compared the Prince of Wales to an artist, because he follows the fox hounds, and sometimes gets possession of the brush, and, as artists use the brush, of course the Prince was a professor of the brush. This is an old piece of wit, and clumsy as it is old. It warrants the application to the speaker of a sharp saying of Thomas Carlyle, the new Rector of Edinburgh University, who, when he was told of a pretentious picture maker, he replied, "Ah, he thinks himself a great artist because he uses a big brush." However, Sir Francis Grant is said to possess a cordial, hilarious manner, and no doubt he made his remarks feel a little more lively than they read. Be this as it may, the Prince of Wales was bored, and wanted to go. It is said that it was hinted to Earl Derby to be brief, who was, however, too proud to abridge on compulsion even for a Prince, and actually made a purposely long speech. At length the Prince rose; then the meeting broke up, it being the custom for the chairman to attend on a Royal guest when he rises to depart, and Mr. Disraeli's speech, prepared for delivery, never came off.

The Prince himself made a very good speech. Prince Alfred's was to the purpose, and he spoke gracefully of Maclise's "Death of Nelson," a picture in the gallery this season. But the Prince of Wales ventured to give an opinion of his own on another picture—not known and approved like Maclise's—"Volunteers Firing at a Point." Nothing could be more modest and becoming, or show more good taste and good feeling, than his mention of the late Sir Charles Eastlake: "I cannot forbear offering *my small tribute* to his merits, having always considered him as an old friend, and having, indeed, known him since my childhood. I shall always be ready to do *my little best* to promote the welfare of art and science." The marks of a genuine speech are here.

Complaints have been made through the press that His Royal Highness was wanting in courtesy to the company, and, bored or not bored, he should, as a gentleman, have stayed it all out; and he has been rather sharply reminded that he "owes duties to society," and so forth. It seems very bad taste to be reminding His Royal Highness, as has been done oft of late, that he does not give value for the money he receives. What the nation chooses to give should be given ungrudgingly, and he who receives it should be left in the enjoyment of it, without unhandsome reproach or reminder. Why should the Prince stay in any assembly when he is well tired of it? It must disincline him to go to public meetings when it is made a drudgery to him. The remedy seems to be to relax the conventional rule that breaks up a dinner-party when the Prince departs. There would be more freedom for the Prince if he were allowed to come and go, like any private gentleman, and the meeting proceeded with its business or pleasure afterwards to the end. In cases in which the Prince was interested, he would stay, and his staying would be a real compliment. Now he can pay no compliment of the kind. If he goes, he must stay, or give offence by leaving. We rather like him for leaving. It shows a resolution to act on his own taste, and not to stay in a formal, hollow, insincere way, as though he liked a thing when he did not.

It is quite true that a young man, of high station or low station, should learn to defer to the comfort of others, and should be willing, at inconvenience to himself, to show them deference and respect. This is duty and gracefulness of conduct; but the charm of this consists in its being done voluntarily, and not from conventional coercion. We take it that the Prince is more likely to do it as a personal and spontaneous thing, than otherwise; and we rather regard his behaviour at the Royal Academy dinner as proceeding from an unconventional spirit than from rudeness or thoughtlessness.

On the occasion of the Prince meeting the Princess at Gravesend, when she arrived in this country at the time of her marriage, the Prince went up to her and kissed her openly and heartily, in a very English and affectionate way. This was not etiquette, but it was nature, and youth, and truth. Nobody liked the Prince the worse for his frankness and demonstrativeness of affection. Princes get spoiled soon enough by custom, and put on the cold, formal politeness, which has grace without heart and courtesy without sincerity.

Her Majesty the Queen has always been remarkable for sincerity of character, and for a certain unconventional spirit, which has done more than all courtly forms to endear her to the nation. At one of the first *levées* she held after her ascension to the throne, she observed the late Mr. Hume at some distance from her. She rose and went to him, and, giving him her hand, said she was glad to see an old friend of her royal father. Many similar acts of spontaneity are recorded of Her Majesty. Her letter to the poor widows of the Hartley miners, 200 of whom perished so tragically some time ago near Newcastle, will be remembered for generations in that district. Her Majesty's late letter to Mr. Peabody is another example of a noble individuality of action. Official letters and public addresses in England are usually poor, tame, formal, conventional, spiritless things. England scarcely ever shines in those matters. But the letter to Mr. Peabody was a brief, forcible, graceful production. It was a worthy example of a royal letter. It would be a very fortunate thing if Her Majesty would compose her own speeches to Parliament. That meaningless insipidity, that official mockery of sense, that great State parade of saying something without expressing anything, would then have some human interest in it. What we want is to see our great personages endeavouring to do what common people should endeavour to do—try to do the best they can, and take the risk of that. As an eminent teacher lately said, "Those who are afraid to take aim never hit anything—to be always safe is always to be feeble." This is why we are glad the Prince of Wales has shown some individuality of character. We would, if we may venture to express the opinion, rather see him aim at being right than at being safe. A few errors of individuality are better than the faultless monotony of mediocrity. Even conventionality will be better if progressive. Uniformity judiciously broken up is a great gain to courts and to people.

Textile Manufactures of England.

BY WILLIAM ROSSITER, HISTORICAL SCHOLAR OF WORKING MEN'S COLLEGE.

IV.—GENERAL VIEW OF THE MANUFACTURES.

Having sketched the progress of the textile fabrics till the period of those great inventions which have so greatly increased the extent of the manufactures during the last hundred years, it will be necessary, for the better understanding of the nature of these inventions, to take a general view of the manufactures, the nature of the raw materials, of the different processes by which these raw materials are made into clothes, carpets, silks, calicoes, &c., and of the factory system generally. The present paper, therefore, will offer a brief outline sketch of the cardinal facts of the textile manufactures of England.

The raw materials of England's chief textile fabrics are cotton, wool, silk, and flax. Cotton grows in the flower of one kind of plant, flax is the fibres of another; wool grows on the backs of sheep, and silk is spun by small worms called, for this reason, silk-worms. Thus, of the four classes of raw materials, two—cotton and flax—belong to the vegetable, and two—wool and silk—to the animal kingdom.

Cotton, often called cotton-wool, grows in bunches of short fine white or grey fibres, varying from less than one inch to nearly two inches in length. These short fine threads are, by spinning, made into a continuous thread of any required length and thickness. A number of these threads being laid one way, and a number of others laid across them, the two sets are interwoven together, making a continuous sheet of the material.

These two processes, spinning and weaving, are the cardinal ones of textile manufacture: there are innumerable other processes, but they are all subordinate and subsidiary to these two—spinning, by which long continuous threads are prepared, and weaving, by which these long threads are interwoven to form fabrics of different kinds.

Wool also grows in bunches of short fibres, which are spun into long threads and woven into woollen cloth, carpets, blankets, &c. Silk is already in long threads when spun by the silk-worms, but these are too fine to be of any strength, and several of these are twisted together to make one thread strong enough for weaving. Flax, the fibre of a plant, has to be cleaned and separated into finer fibres before it is fit for weaving into linen, cambric, &c.

The chief varieties of raw cotton are American, East Indian, and Egyptian; of wool, English, German, and Australian; of silk, Chinese, Indian, Persian, Italian, and French; of flax, Irish, Dutch, and Russian. Of these, the American products come chiefly to the port of Liverpool; very much of the Indian and Australian to London; and of the German and Russian, to Hull.

The raw cotton is sent almost entirely to the towns of South Lancashire, of which Manchester is the chief; the wool goes to the towns of West Yorkshire, of which Leeds and Bradford are the largest, to the neighbourhood of Glasgow, and to Gloucestershire, of which last-named district Stroud is the centre. Silk is spun in the district lying between Derby and Manchester (Macclesfield being an important centre of the trade), and woven in London and Coventry; silk is also used to a great extent in the weaving of fabrics made of mixed silk and cotton. Flax is spun into thread and woven in linen, cambric, &c., at Leeds and Barnsley in England, at Dundee in Scotland, and at Belfast in Ireland. Only the chief seats of the respective trades are here mentioned, so that the reader may have a clearer conception of the localities of each.

The Cheviot Hills run across the island of Great Britain, dividing Scotland on the north from England on the south. From this range another series of mountain groups run southward towards the centre of England, separating Northumberland, Durham, and Yorkshire on the east from Cumberland, Westmoreland, and Lancashire on the west. From these hills, which thus form a backbone to the North of England, run down innumerable small streams, eventually joining together to form large navigable rivers, such as the Humber and the Mersey.

The greater part of the land eastward of this midland range of hills, and a large tract to the westward of it, consists of coalfields yielding fuel of an excellent quality, in beds of great thickness sufficiently near the surface to be easily worked. The two great necessities of a factory locality, fuel and water, are abundantly present in all the seats of our spinning and weaving industry, for coal and running water are as near at hand at Glasgow and in Gloucestershire as in Lancashire or Yorkshire.

Generally speaking, it will be seen that factories are established in suitable neighbourhoods near the large seaports of the kingdom, a suitable neighbourhood being one where water and coal are easily attainable. These, if not already populous places, soon become centres of population, and, in many cases, towns of considerable size.

South Lancashire and West Yorkshire possess all the requirements of nearness to the large seaports of Liverpool and Hull, of abundance of water and coal, and are now places of vast population. The towns in this district are numerous, and connected by innumerable lines of railways and by canals. It should be carefully remarked, however, that the district has become the seat of factories because of its natural features only, and that the dense population, the railways, and canals are only effects and not causes of this; though these railways and canals have been, to an enormous extent, the means of developing and improving the work of the district.

The same applies equally to the other great centres of textile industry—Glasgow, Stroud, and Leicester—all of which were chosen originally for their abundance of water and coal, and have, in consequence, become centres of dense population, and districts of ample railway accommodation.

A very important cause of England's greatness as a manufacturing country, is the abundance of good iron near the coal districts. English machinery stands very high indeed in the estimation of the world generally for ingenuity of design and excellence of workmanship; but ingenuity and good work would be of little use without an ample supply of material for use. Cotton can be bought almost as cheaply here as in India or America, because it is comparatively light in weight, and freight does not materially increase the price; but the same cannot be said of such heavy substances as coal and iron. Therefore, a country rich in coal and iron, has the materials of manufacturing prosperity, if it have also the necessary ability and industry to use them.

Consolation for the Emigrant and the Sailor.

Among the numerous physical and moral disadvantages contingent upon life at sea, that of a defective and unwholesome water-supply may be safely pronounced the most serious. It is, indeed, a fruitful source of disease, inconvenience, and demoralisation. Cleanliness, which has justly been said to be next to godliness, becomes an impossibility under such circumstances, and the long train of sad consequences thus entailed are known, at least theoretically, to all. Those who are enabled to live at home at ease, experience few of the annoyances arising from a scanty supply of water. Our rivers, lakes, and streams, and the bosom of the ever-bounteous earth, yield abundance of Nature's pure fluid, and science having it completely in its power distributes it with lavish hand throughout our households. Private beneficence, too, has rendered important service to the community in the same direction, and drinking-fountains exist on all sides for the refreshment of the wayfarer. In short, good water and plenty of it is the rule on shore, whilst at sea these conditions are exactly reversed.

We are perfectly aware that, so far as emigrant ships are concerned, much improvement has of late years been effected. Government inspectors now take especial care of those who from choice or necessity commit themselves to the perils and the trials of oceanic transit. They prevent the recurrence of the disastrous consequences which in past times have arisen from neglect, and from the cupidity or thoughtlessness of ship-owners and agents, and they insist upon the observance of all ordinary arrangements for the promotion of the health and comfort of emigrants. Government inspectors cannot, however, achieve impossibilities nor counteract natural laws. They are powerless, for example, in preventing the

deterioration of water from its long standing in tanks and casks. It is true that calculations are made as to the probable duration of each voyage, as to the number of persons to be provided with sleeping room and breathing space between decks, and as to the quantity of food and drink necessary for the sustentation of each passenger and sailor. Upon these calculations the scale of accommodation and of provisions is based. An evil beyond the power of remedy hitherto, has been the undrinkable state of the water on board ship after the lapse of a certain time. When an outward-bound emigrant ship, with its complement of perhaps 400 men, women, and children as passengers, and its fifteen or twenty officers and men for a crew, is on the eve of departure, much space is necessarily occupied with tanks of fresh water. What kind of fluid such of the tanks as remain charged towards the termination of a three months' voyage contain is painfully well known to those who may have been compelled to partake of it, and may be imagined by those who have not. It is simply poisonous in its nature, and destructive to health. Were such a system of water-supply to prevail in our homes on shore, we should be justified in expecting—and especially in seasons when epidemic complaints exist—the worst possible consequences. On board ship, and in company with defective ventilation, it ensures the generation of various diseases, and then exaggerates their virulence and fatality.

It is scarcely necessary to dwell further upon this part of the question of water-supply at sea, for all voyagers are aware of its usually defective nature, and the evils resulting from it. It is one of the banes of the poor emigrant; but, fortunately, it has its antidote, and we shall now endeavour to indicate the direction in which a sure remedy is to be found. It is in the ocean itself. By the processes of evaporation, condensation, and percolation, the ocean feeds our rivers, irrigates the earth, and supplies our springs; and man's ingenuity, availing itself of a knowledge of the action of those beautiful laws, has at length devised a mode of copying them and turning them to useful account on board ship. A very ingenious contrivance has been recently devised by Mr. Graveley, an engineer, for distilling sea-water in large or small quantities, and thus of making the ocean the direct means of supplying ships day by day with the purest fresh water.

Steam, that faithful and obedient minister to human comfort and convenience, is the agent and prime mover in effecting this admirable result. A small high-pressure steam-engine is, indeed, the main feature of the Graveley distilling apparatus; and, as will be seen presently, distilling is not its only duty. Mr. Graveley has made it a mechanical servant-of-all-work into the bargain. Connected with the crank shaft of the engine, which latter in an ordinary emigrant ship would be placed in the galley or cooking-house, are two pumps. One of these draws water from the sea through a suction pipe, the mouth of which opens out a few feet below the water-line of the ship, and forces it through a series of small pipes into a large receiver or boiler. There it is converted into vapour by the application of heat. The vapour, passing afterwards into a vessel surrounded by cold water, is condensed, and mixed with a certain amount of air introduced under pressure. It is drawn out sweet and fresh as spring water. Such, in brief terms, is the whole of the arrangement for converting salt water into fresh, or rather for separating the salt held in solution by the sea, and leaving the latter totally unimpregnated with saline matter. The apparatus may be made of any capacity. That suitable for an emigrant ship, with 400 or 500 passengers on board, occupies a space of about eight square feet, and yields readily 1,000 gallons of water every day.

The inventor has not rested content with this invaluable result; he has utilised the distilling engine to a far greater extent. The boiler of the engine is in connection with a series of cooking stoves and ovens, and the surplus steam from it, instead of passing idly into the air, is made to boil, bake, or stew the solid food for the whole of the passengers and sailors. In addition to this, the engine is made, by means of trimetres, easily engaged or disengaged, to furl the sails, to lower or raise the topmasts and yards, to lift the anchor, to warp the ship into or out of dock, or off a lee shore, and to load or unload her cargo. By making a slight alteration in the valve gear, the pump for supplying the distilling chamber is converted into a very powerful agent for suppressing fire, and is at all times available for washing decks, &c. Lately, Mr. Graveley has added to the engine a bilge-pump for discharging such water as would otherwise accumulate between the inner and outer planking or plates of the ship, and a revolving fan for withdrawing from the hold, cabins, and berths, vitiated air, and supplying its place with pure air from above.

It only remains to be said that the cost of the engine and apparatus is not great in proportion to their exceeding usefulness and value, and it becomes really inconsiderable when the economy it effects in regard to stowage-room is remembered. In place of encumbering the vessel with tanks and casks, the space they would occupy is available for a largely-increased and far more profitable cargo; and a few voyages under such circumstances repays, therefore, the expense of the whole apparatus. It constitutes at once a comprehensive, labour-saving machine, a distillery, and a self-acting kitchen, if that term be nautically admissible.

We believe that Mr. Graveley contemplates making his universal steam-engine provide batches of bread every morning for the comfort of passengers, instead of the "hard tack," in the shape of sea-biscuits, with which at present they are only too familiar. Some of his experiments in this direction have already been attended with considerable success, and there is little doubt that in time the task will be completely accomplished. It will not be denied, in presence of the foregoing facts, that the title of our article is a just one, or that we have succeeded in affording a prospect of coming consolation for the emigrant and the sailor.

SIR W. HUTT, M.P., ON INDUSTRIAL EXHIBITIONS.

At the recent opening of the Gateshead Industrial Exhibition, Sir W. Hutt said:—"The gentleman who first originated these exhibitions in this country, had before him this idea, that the exhibition might be a means of affording to the working classes occupations agreeable in themselves and ultimately profitable, and which were more worthy of their occupation than the listless and grievous practices to which they were often condemned, and far more desirable than the contaminating influences of the public-house. Well, this was a kind and generous object; I may give it a higher title still, and say it was a patriotic object. If we are to love our country as rational beings should love it,—not for its sticks or its stones, not for any accidents of soil or climate, but for the air we breathe, the institutions that ennoble the mind, and the means that make it a living country to men;—if these are objects that we should love in loving our country, I can conceive of no higher aim of patriotism than the endeavour to exalt the moral nature of those millions upon whom the highest destinies of our country must ultimately depend. And I know that the thoughtful and reasonable men amongst the working classes—and there are thousands of them—entirely concur in the object thus proposed to them; but I know also that unless those institutions had received the support of other motives than this, they never would have enjoyed that popularity and support of the working classes which they have everywhere received. Now, let me speak plainly upon an important subject. There is going on in this country a contest between the representatives of capital and labour such as, I believe, never before occurred in the history of European civilisation, such, perhaps, as never before occurred in the history of the world. The two parties are each of them anxious to acquire for themselves—as it is most natural that they should—the largest share of the advantages, the credit, and the profit of their enforced and necessary co-partnership. The efforts of the working men to stand up for themselves are shown in Co-operative Societies, in Working Men's Clubs, in exhibitions such as this, and so long as the struggle is continued on either side by means so honourable and so laudable, I can only say, in the language of the umpires of ancient chivalry, "Set on, and God defend the right." But, gentlemen, let us not defend—let us not undertake the battle of what is right—let us not fight the battle of truth—with the weapons of error. Depend upon it that if either party have recourse to violence or wrong in support of their views, they will embitter, and they will degrade a most legitimate contest, and they will render any permanent or satisfactory settlement of it almost impossible. I think it is one of the great advantages of such an institution that it has a strong tendency to introduce a spirit of conciliation and of mutual concession into the struggle that is going on. Here the employer of labour, the capitalist, may learn what the working men are capable of without his intervention or his patronage. By the study of such an accumulation of work as he has assembled in this exhibition, they will be led to form a just and generous estimate of that brave and patient industry, that singular ingenuity, that occasional genius here and there, and those marks of artistic merit of which the working men are now found capable of giving you examples. On the other hand, the working men may learn the great advantage to themselves of that combination of labour, of that division of employment, of the use of the most perfect, and, consequently, the most valuable tools and machinery, the value of the most extensive and the most advantageous markets, all of which things are obtainable by means of the employment of capital. I think, then, that if the two parties will study these and similar exhibitions with attention, if they will only read these things aright, they must come to a conclusion tending to bring their great industrial dispute to a termination satisfactory to both sides."

Facts and Memoranda.

Bessemer Steel in France.—It appears from returns prepared by the committee of ironmasters that in 1863 there were 1,856 tons of Bessemer steel manufactured in France, in 1864 6,750 tons, and in 1865 9,751 tons.

Propulsion of Shot.—It would appear, from experiments conducted in America, that shot does not begin to move until a large proportion of the charge behind it has been ignited, and that it moves through one-half to one-quarter its diameter before the whole is ignited.

A desire for the opportunity for gymnastic exercises appears happily to be spreading in England just now. A gymnasium has been established in Whitehaven. Arrangements are being made for opening one in Reading. In Liverpool is to be found one of the most perfect yet established, the cost of which has been about £14,000. In Manchester they are only waiting to see the result of the movement in Liverpool.

Consumption of Iron in France.—Some statistics have been published to show that the consumption of iron in France is much less than that in England, in proportion to the population. The consumption of cast iron in England in the year 1863, with a population of 26,800,000 souls, is set down at 4,357,000 tons, or about 230 lb. weight a head; while France, with a population of 37,500,000, consumed only 70 lb., or one-third of the consumption in England. The consumption in France is now rapidly increasing, in consequence of the number of new buildings in progress. Ten years ago almost all the railway bridges were built of stone, in consequence of the high price of iron. At present similar works may be constructed at a less cost in iron than in stone.

The Worcester Pottery Manufacture.—The Worcester manufacture appears to have had a political origin, and to have been fostered with a view to reviving the decaying trade of the "faithful city" by an infusion of new blood, and an addition to the voters, in order to carry an anti-Ministerial candidate into the House of Commons. Practically, however, the chief promoter was Dr. Wall, who, after a patent taken out by Thomas Frye, in 1749, succeeded in producing an "artificial porcelain," which, for "translucent fabric, perfect unison of body and glaze, and general approximation to its great prototype, the porcelain of China, has no rival." Dr. Wall's love of art led him to the study of a product in which so much taste could be shown, and his technical skill enabled him to overcome difficulties which had baffled his predecessors. Whether Dr. Wall and Thomas Frye hit upon the same idea together by one of those curious accidents which have frequently occurred, or whether Dr. Wall was stimulated by Frye's patents, is not quite clear, but a Porcelain Company was formed at Worcester, and thus the famous manufacture commenced. The pottery was erected on the Warmstry House site, sloping down to the river, in May, 1751, and the manufacture rapidly increased.

Shearing Sheep by Machinery.—An American has invented a sheep-shearing machine. With two men to hold the shears and one to turn the wheel, the machine clips sheep with an almost unimaginable rapidity, as there is no expenditure of muscular labour besides turning the wheel, which is not harder than a small spinning-wheel, and the whole machinery does not occupy more room than such a wheel. A new principle in mechanics has been developed in this invention, which is the secret of its success. This is a flexible shaft, through which the power is communicated from the driving-wheel to the shears, which are kept rapidly clipping as long as the driving-wheel turns, no matter in what position they are held, nor how much the driving shaft is contorted, even to bending it around the body of the sheep. This driving shaft, about three feet long, is a spiral brass wire, one end of the coil being connected with a small wheel attached to the butt of the blades of the shears, and the other to a pulley driven by a band on the end of an arm, which is partially flexible, attached to the small frame that holds the driving-wheel. On the opposite side is another arm and shaft and shears, for another shearer, each working independent of the other. The shears are made with guards, so that all that is necessary is to hold them level and steady on the skin, pushing them forward as fast as possible.

MONEY PRIZES,

TO BE COMPETED FOR BY

WORKING MEN.

TWENTY PRIZES—TEN of FIVE POUNDS each, and TEN of THREE POUNDS each—are offered by Messrs. Cassell, Petter, and Galpin. One Prize of Five Pounds for the Best Essay, and One Prize of Three Pounds for the Second Best Essay will be given. The list of subjects and the conditions of competition appeared in Nos. 10 and 11 of the Working Man.

We have much pleasure in announcing that the following gentlemen have kindly undertaken the adjudication of the Prizes:—The Right Hon. Lord Houghton; Right Hon. Lord Lyttelton; Right Hon. Lord Talbot de Malahide; Lord Milton, M.P.; Charles Buxton, Esq., M.P.; John Stuart Mill, Esq., M.P.; Rev. Charles Kingsley, M.A.; Rev. F. D. Maurice, M.A.; and the Rev. J. Begg, D.D.

Rest-Day Doctrines.

"The world is too much governed" is a remark constantly receiving uncomfortable illustration. Nearly all our Acts of Parliament which prescribe duties to be performed are so many directions to persons to do what they ought to do of their own accord. Lord Chelmsford's Bill to prohibit Sunday trading is of this description. No doubt tradesmen require relief from the obligation of keeping open their shops on Sundays. It does not meet the case to say, "A shopkeeper need not open his shop on that day, unless he pleases. There is no law to compel him to do so, and there needs no law to prohibit him from doing what he is not disposed to do." Though there is no legal law to compel a tradesman to open his shop on a Sunday, there is a social law that practically compels it. In business a man must do what his neighbour does, or lose his customers and fall behind. The moment one offers advantages or a convenience, the well-known sheep-dance follows, and every shopkeeper has to imitate the one who leaps over the stile. This seems an absurd movement, and, no doubt, might often be avoided; but, as a rule, it has to be done. This is the best argument on Lord Chelmsford's side. There are instances in the history of working men exactly resembling that which we have described. Some years ago an Act had to be passed to prevent the employment of children in factories until they were of a certain age. The interest of the parents was to keep their children at home, and at school, until they were well grown and well informed, or tolerably well instructed in the rudiments of knowledge. Any one would have said that Trades Unions would have enforced a Factory Act among the parents, without the aid of the law. The mere pride of the workman should have kept his children at home. There should have existed a sort of public opinion in every factory, which should have branded as disgraceful any parent who sent his child to the workshop during tender years. But none of these forces or feelings operated, and the law was called in, to effect what ordinary sense and common feeling should have done. There was no law to compel parents to send their children to work while they were young, yet they did it; indeed, it required a law to restrain them. This is one of the most humiliating social facts of our industrial history.

However, the law which rightly stepped in to protect children from their parents, declines to step in to protect tradesmen from their customers. The grown-up man of business should, if anybody should, be able to protect himself. And this is the chief side of the argument against Lord Chelmsford's Bill. And the question arises, Are there no methods of attaining the end in view, without having recourse to penal statutes? Law itself is but a choice of evils. Statutes imply new perplexity, and cumbrous and expensive machinery for their enforcement. A staff of lawyers and judges are needed, or made additionally necessary, for the interpretation of each new statute; and increased police machinery is another result. That nation holds the most honourable place that is governed by laws simple and few. If a great book be a great evil under any circumstances, a great statute-book is a greater, under all. A great legal writer has said that "such has of late years been the overloading of the statute-book, that men turn in despair from any attempt to know its contents; and instead of there being laws few and plain, but certain and constant, they are endless, intricate, involved, and contradictory." No new law, therefore, is admissible, unless a very clear case can be made out for it. This has never been done on behalf of further legal interference with the Sunday. Many persons are of opinion that steps might be taken, both by traders and purchasers, to put an end to the evil complained of on all hands.

Everybody is agreed that a day of perfect rest once a week is desirable; indeed, the doctrine is becoming pretty general that two days' rest would not be amiss. When Mr. Disraeli was a young man, he tried to sum up, in one of his little-known "Runnymede" Letters, the characteristics of the English race since the Reformation; and he resolved them into one word—"Industry." But, nevertheless, John Bull likes his leisure. The portrait which *Punch* always gives us of him is that of an elderly gentleman, with an eye to business, obesity, and ease. Over-work has plainly had its day. Medical people have set their faces against it. Doctors die of too many patients; statesmen, of too much responsibility; men of business, of too many cares. And now Mr. Edwin Chadwick has come forward and proved that too much work does not pay. There is no doubt that he will carry the day. Over-work is not agreeable, and when it does not answer it is plainly a mistake. The drill-sergeant knows that the soldier deteriorates in discipline if he has too much of it; two hours' drill per day is all the strongest man can go through with advantage. Mr. Chadwick has proved that a pupil cannot learn if he is kept at his tasks more than a certain time, and that workmen will do more, and do it better, if their hours of labour are few, and within the limits of their natural strength. The tendency, therefore, of society is to short time—to less labour and more rest. The short-time movement has grown into fashion, and is destined every year to extend itself. General tradesmen begin to shut up earlier; and the same rule is capable of being extended to provision-dealers and markets. The Saturday half-day holiday is being extended, and in some manufacturing districts the whole of Saturday is being claimed, and in some cases is conceded.

The reason why Sunday trading is admitted to be a necessity in some districts is owing to the fact that numbers of people of the poorer class are kept employed until nearly midnight on the Saturday, and receive their wages so late that neither themselves nor their families have opportunity of making purchases at other times than Sunday mornings. To make a law, therefore, is—however desirable, morally or religiously—attended by privation upon classes who socially fare the hardest, and therefore are entitled to the most indulgence. To extend the Saturday holiday to these classes, to abridge their hours of labour, is a far more merciful thing than coercing their purchases by law, and would answer the end in view much better than any law would do it. Another mode open is to create an improved public opinion among purchasers. The rich have given up, or are giving up, the habit of making late purchases on any days. The working class ought to be taught to do the same thing. It ought to be held to be disgraceful in a working class family to go making purchases late on a Saturday night. If they are obliged to do it they ought to complain of it, and protest against it; and unless obliged they ought never to do it. Trades Unionists should make speeches on this subject, and write tracts against it—call attention to it in every way, and influence all the families whom they have the means of reaching, to act upon this principle. Energetic action in this direction would very soon overtake the evil of Sunday trading, and correct it. We think this plan preferable to a combination among tradesmen to refuse to sell, as this would act upon the poor, who have no choice but to buy on Sunday, with all the force and privation of the law against it. The *Pall Mall Gazette* is in favour of this plan; and it certainly would have the effect of liberating thousands of assistants, who are now obliged to work late on Saturday and on Sunday too. By one plan or the other, and perhaps better, by both united, we are sure the evil of Sunday trading could be put an end to without the suspicious aid of Lord Chelmsford.

GRIND THE TOOLS.

Keep the tools sharp, or they will not cut. A dull tool wastes time, and he who permits it to work, when in that condition, is a dull fellow. The best turners are those who have the sharpest tools; the most successful surgeons use the keenest knives; and the most enterprising and energetic men in civil life are those whose wits have been early ground sharp, and whose perceptive faculties have been whetted by sore experience in early life. A dull tool is a useless implement, and a thick-headed, unobservant person is the only one who should be found wielding it. The obtuse edge neither cleaves nor separates, but bruises and works off by attrition particles of the substance on which it operates. Grind up the tools and sharpen the wit as well; if one is keen, the other will, in all probability, be in a similar state, from force of sympathy alone. A boy with a dull pocket-knife is one who swings on the gate, and who dodges his duty; he is one who, in after life, will be a dunce and a cumberer of the ground; he will add nothing to the world of science, neither will he take from it; his existence is merely animal, his thoughts and ideas—if he has any—wholly conventional. His comrade, with a keen blade, makes models of machinery, of boats or steamers, and in time he becomes a George

Steers, or so develops his mother-wit as to be a decided acquisition to the community. Let us have all the tools in good condition—sharp, trenchant, and always ready for service; then, and then only, will the result produced be equal to the time and labour expended.—*Scientific American.*

*Electrotyping.**

ELECTRO-SILVERING.

Baths.—It is by means of the double cyanide of potassium and silver, dissolved in an excess of cyanide of potassium, that electro-chemical silvering is accomplished. Several methods may be employed to arrive at this result. We shall give the simplest.

Dissolve 4 lb. of silver in 13 lb. of nitric acid, and evaporate the solution over a spirit-lamp until the nitrate of silver fuses. In this manner not only is the excess of acid driven off, but the small quantity of copper (which is always present, in the purest commercial silver) is reduced also. The nitrate of silver is then dissolved in 5 gallons of distilled water.

On the other hand, dissolve 4 lb. of cyanide of potassium in 17 pints of water. This solution added, little by little, to the solution of nitrate of silver, causes a precipitate of cyanide of silver and the formation of nitrate of potassa. This operation, carefully conducted up to the point when the addition of a small quantity of cyanide no longer causes a precipitate, the nitrate of potassa may be removed by decantation. The precipitate remaining at the bottom of the vessel is washed with distilled water, and immediately dissolved in 4 lb. of cyanide of potassium, then sufficient water added to make up 20 gallons. The bath is not immediately fit for working. Before it will yield a good deposit, an equal quantity of an old bath must be mixed with it, or, to give it the qualities of an old bath, it may be boiled several hours; or lastly, and which gives the surest result, add 2 lb of yellow prussiate of potassa for every 4 lb. of silver; but this last composition of a bath—the most commonly employed—is not adapted for brilliant silvering.

The solution of silver thus obtained is put into large wooden baths, lined with gutta-percha, in order to prevent the absorption of the liquid. The vat is divided lengthways by rods, to which the anodes of pure silver intended to maintain the bath in a constant state of saturation are attached. All the anodes, connected together by a copper frame, communicate with the positive pole. Between the anodes, the copper rods communicate, by a series of isolated frames, with the negative pole of the battery. Upon these the hooks holding the articles to be silvered are hung. The articles are then washed in potash ley, rinsed in water acidulated with nitric acid, then passed to the acids, or pumiced, according to the nature of the metal; lastly, dried in hot sawdust. This done, the articles are weighed, and the amount of metal deposited is ascertained by the difference between their weight before and after silvering. As the articles are liable to become oxydised by exposure to the air, and greased by contact with the hands in weighing, before they are immersed in the bath they are submitted to a second cleaning, which consists in immersing them in benzine, in water acidulated with nitric acid, in nitrate of mercury, and rincing in fresh water. The articles become coated immediately they are immersed in the bath. For a bath containing 130 gallons of liquid, four Bunsen's elements, measuring 100 inches by 160, will suffice to deposit nearly a pound of silver in four hours.

Brilliant Silvering.—The silver deposit from the cyanides is usually *mat.*

By adding a little sulphide of carbon to the silver bath, the metal is deposited in a brilliant state. What takes place in the liquid to produce this result is not clearly understood. The best manner of employing the sulphide is to put into a glass-stoppered bottle 1½ oz. of sulphide of carbon to 6 gallons of silver bath, and leaving them in contact 24 hours: by this time a blackish precipitate is formed, and the solution is ready for use. Before each silvering operation 1 part of this solution is added to 100 of the bath, and immediately the deposit of silver becomes as brilliant as if it had been polished at the wheel.

The metal employed in the construction of the articles to be silvered or gilt is brass, composed of two-thirds copper and one-third zinc. It serves for all kinds of turned, stamped, and hammered objects. Another alloy of copper and zinc, in different proportions, specially arranged for this kind of manufacture, is employed for cast and chased works.

The first alloy serves to make the forms, the second is employed for what is called the *furniture.* If the forms are round or oval, they are turned at the lathe. From the first model made in plaster, the article to be executed is turned in wood; then a series of moulds is established, which are intermediate between the articles to be made and the sheet of brass which is to be chased. These moulds are called mandrins. The metal is raised or depressed by making it take the shape of the mandrins by means of steel tools of different shapes, according to the effect to be produced. Between each stage of operations the article is heated in a reverberatory furnace. A prize cup, for instance, requires five mandrins and four heatings in the furnace. If its form is not irregular, the last mandrin is made of boxwood, divided into several pieces, retained in position by a central core of metal, which, being withdrawn first, allows the other pieces to come out easily. If the forms are square at the bottom or sides, the employment of iron matrices is necessary.

TURNING OVALS.

* Continued from page 330.

Political Facts.

It would puzzle the Parliamentary statisticians to explain how it is that so fashionable a town as Brighton always has Liberal, indeed Radical, members. George IV., when Prince of Wales, built a pavilion there; it stands there still, and Royal ideas, no doubt, float about Brighton yet. Nevertheless, the town elects Radical members, and the fashionable people do not flee from it.

Mr. Roebuck relates, in one of those political pamphlets which first made him famous, that he knew a distinguished soldier (probably the Duke of Wellington) who, in encountering a friend, said, "Where do you come from?" The answer was, "I have just come from Mr. O'Connell." "Did you shake hands with him?" was the next inquiry. "Yes." "With which hand?" "With my right." "*Then shake my hand with your left!*"

Political toleration has progressed since then, and Brighton partakes of it, and is rather proud than otherwise of its Liberal members. A franker, more honest, or more spirited English gentleman never entered the House of Commons than Mr. Coningham, the late member. Professor Fawcett has succeeded him, and Mr. James White is the senior member, who, from his majestic stature and resonant voice, was called the "Plymouth Sound" when he was member for Devonport, and is now regarded, in the best sense of the term, as the "Brighton Pier," which word might be spelled with a double *e.* Constantly saying useful things, and always doing sensible ones, he moved, two years ago, for a Parliamentary report, showing the population and electors of the United Kingdom. Some time ago Lord Elcho was, very properly, anxious that an idea should be acted upon, upon which Mr. Edward Chadwick had laid great stress, namely, that the new Reform Bill should be based upon statistical information, and took credit to himself for having induced the Government to supply to Parliament the information upon which their Franchise Bill was based. But Mr. White was before his lordship in this sensible proposal; and a return which Mr. White obtained in 1864, and to which too little attention was paid at that time, Government have re-published in 1866. A more curious and instructive document has seldom come before the House. One department of this return gives the population of English counties in 1821, 1831, and 1861, and shows the increase and decrease of population up to 1861. Since 1831 the population of Northern Devon has decreased nearly 2,000; the population of Western Sussex has decreased 1,500; Northern and Southern Wilts, Montgomery, and Radnor have decreased. In the Parliamentary boroughs and cities, Laun-

ceston, Honiton, Lyme Regis, Lymington, Taunton, Arundel, Salisbury, Bewdley, Kidderminster, Frome, Westbury, and Knaresborough, are dying constituencies. Stroud has decreased 4,000; London (city) has decreased 10,000. London is alive, no doubt, but its population has fled to the suburbs. They are all back during business hours; the other places have lost them entirely. Mr. Howells, who recently published a charming volume on "Venetian Life," states that Bohemian organ-grinders have "a dead-in-earnest manner" of playing. This seems to be the way with numerous places in England. Many counties and boroughs have remained stationary for thirty years, neither increasing nor decreasing, neither dead nor alive; others are dead and decaying; still they have members of Parliament. They ought to be represented by ghosts of former members. The Davenport Brothers might arrange for this.

In 1832 the Reform Bill created a new set of £10 voters, or, as the late Mr. Fox, member for Oldham, used to style them, "a Worshipful Company of Ten Pounders." But it left in many boroughs a class of voters who were known as "freemen, scot and lot voters, pot-wallopers, and the electors with ancient right qualification." In Chester there remains 1,300 of these curious creatures; in Liverpool, 1,300; in Leicester, 1,300; in Norwich, 2,000; in Nottingham, 1,600; in Stafford, 1,000; in Coventry, 4,000; in York, 2,500; in Kingston-upon-Hull, 1,300. But experience shows that the "freemen" are not free, and are well known to the "man in the moon;" and the "pot-wallopers" deserve boiling down, and there is fear that their very jelly would be venal.

Mr. White's return also shows the number of square miles occupied by each borough under the Reform Act of 1832. Wallingford includes 25 square miles; Buckingham, 28; Bodmin, 26; Tiverton, 27; Wareham, 47; Christchurch, 35; Petersfield, 35; Woodstock, 37; Wenlock, 73; Eye, 30. While many boroughs have scarcely half a square mile, some of the most populous districts have the smallest area.

Another division of Mr. White's return shows that the English counties pay three millions and a half of income-tax; the Scottish counties less than half a million; Irish counties more than the Scottish counties, but still less than half a million. The English boroughs pay five millions; the Scottish boroughs half a million; the Irish boroughs a quarter of a million. All England pays eight millions and a half towards the expenses of the State, in the shape of income-tax alone; Scotland less than a million, and Ireland three-quarters of a million. Mr. White's return shows under what schedules this money is levied, and how much each city, borough, and county contributes to it. It is, in this return, also shown that there were, in 1831, 75 boroughs with populations of less than 8,000 each, which returned 118 members, and that 53 of these boroughs still remain, with populations of less than 8,000, and nevertheless return 83 members. The total number of persons in these 53 boroughs is only 314,000; while there are, as the same return shows, 15 municipal boroughs, 44 towns, and 12 metropolitan parishes, including an aggregate population of upwards of one million of persons, who have no representative. We have omitted odd numbers and taken gross results—rather under than over. Nothing makes statistics so tiresome as enumerating fractions of amounts, which nobody can remember and nobody cares for. The gross approximate total is all that concerns those who reason upon figures; the fractions concern alone the arithmetician or mathematician, who uses them as bases of recondite calculations.

The above political facts will enable any reader to understand many discussions as to the statistical foundations of the new Reform Bill, intended to afford a better representation of the working classes; and for sevenpence-halfpenny Mr. White's Return of Population and Electors, No. 259, can be purchased at the Parliamentary Paper offices.

French Imports of Wrought Iron.—The wrought iron imported into France for building purposes during the first three months of the present year amounted to 8,013 tons, and the cast iron to 3,735 tons. The wrought iron imported during the corresponding period of last year amounted to 3,097 tons, and the cast iron to 2,943 tons, showing that the importation of wrought iron increased this year by 158 per cent., and the importation of cast iron by 26 per cent.

Co-operation giving an Account of Itself.

We are glad to see that the newspapers have given an account of the pleasant four o'clock tea held on the 10th instant in the Town Hall, Manchester, at which Thomas Hughes, M.P., presided, when the work-people, friends, and shareholders of "Greening and Company, Limited," met together to celebrate their first co-operative dividend. We trust that Messrs. Greening, Limited, will meet with unlimited success. This company of wire-workers have been in operation about half a year. Mr. E. O. Greening is a zealous friend of co-operation, and the work-people were promised a share in the profits made by the company. To the surprise of Mr. Hughes, and many other persons also, a profit of fifteen per cent. has been made. Everything has favoured this co-operative scheme. A fire broke out at the factory, and stopped all business for a time; but the fire had the discretion or consideration to break out before the company had received the transfer of the concern, and so the loss fell upon somebody else. The fire has kept its place since. The directors of the company have provided that five per cent. of the profits made shall be paid to the hands. This is keeping good faith, and will produce good results. This company, as we have said, has not been in existence long, and we must wait awhile before it can be seen what elements of permanency and success this form of manufacture can secure. We expect it will answer well.

In the course of his address Mr. Hughes contrasted the present state of the co-operation movement with its condition fifteen years ago. About that time he and other gentlemen in London, who were much interested in the subject of association, came down to Manchester by the invitation of working men in different parts of Lancashire who were already endeavouring to set up co-operative societies. But at that time there was no law under which they could be registered; the old partnership law made every member a partner, and if one incurred debts without the consent of the rest, he might take the goods of the society, and there was no remedy except a Chancery suit; or if the society had to sue anybody who had contracted with them, they could only do it by making every member a party to every proceeding in the suit or action. A conference was therefore held with the working men at the "Moulders' Arms," and they had a very satisfactory talk over the line of action to be pursued, and the amendments of the law to be promoted. Nobody outside showed any interest in the subject then; but now the case was very different. Some of the most eminent men in the country wrote to express their sympathy with the principles of this undertaking, and on this platform were some of the leading gentlemen of Manchester. The change in the law had been not less remarkable. In the very first year after that conference in Manchester, they managed to carry the Industrial and Provident Societies' Act, by which all the early associations and stores were registered; and this was the first act that recognised the principle of dividing profits among those who laboured, as contra-distinguished from dividing them merely upon capital subscribed. Many acts had been passed since, which enabled these societies to register, or get the benefits of a legal standing otherwise than under that act. It was now competent for co-operators to associate merely as the old joint-stock companies did, a number of small shareholders putting together their few pounds or shillings, instead of richer men putting together their hundreds or thousands to form the capital of an undertaking, and these societies might divide profits according to the old method of dividing, simply upon the capital subscribed by each member. On the other hand, it was competent for them to carry out to such extent as they might deem advisable the other principle of the sharing of the profits between all those who contributed to the joint work. Whether they were co-operative stores, or associations of workmen, like the Hatters' Association of Manchester (he hoped it existed still, for it made very good hats, which he had worn), he sincerely wished they might adopt the latter principle.

After controverting various assertions by writers in the *Fortnightly Review*, and other periodicals, he referred to the change in the law which met one of the besetting difficulties of the co-operative system—the want of the business experience and talent of the employer class to preside over the operations. "It was now possible for great employers to admit their men to share in profits without encountering any interference with the management on the part of those who thus participated in its results. He believed this company had done rightly and wisely in resolving at their general meeting, without one dissentient voice, that when their profits exceeded a certain amount, a part should be given to those employed, even who were not shareholders. He believed it would have a beneficial influence upon all the work-people, that they would work the better for it, and begin to see the real meaning which underlay these partnerships of industry. He hoped the shareholders would have faith in their principles, and work this great experiment through fairly to the end. They were right in believing in a human fellowship which should bind together all who were connected in any work on the face of this world, and the more they realised this the more they would feel that this nation was one great family—that, throughout society, 'where one member suffered all members must suffer, and where one rejoiced all would rejoice together.' The nearer we could in our industrial operations, as well as in our common life, come to the great maxim of doing as we would be done by, the better for ourselves and for our country. Many people called this sort of talk 'crotchets,' and said it was bringing Christian principles into places where they had no business. But he utterly denied this, and refused to have one set of principles for the workshop and another for his common life. In so far as we earnestly endeavoured to work upon the highest principles, and to accept nothing less than the highest principles in every work, so much the more successful should we be. Nothing worthy of being called success, and which would do good to our fellows as well as to ourselves, could be achieved, unless we adhered to those, the very highest principles ever enunciated on this earth. Upon the honesty with which we endeavoured to work out these principles, in every department of life, all social progress must depend. In as far as we did it, we should find a wider education, a truer moral life, more temperance, more moderation in all our actions, more self-respect—to sum up, in fact, a higher and truer civilisation. It might be called a dream, but if one's belief in a good time coming, through the development of these principles, were a dream, he would sooner dream it than be awake amongst the terrible facts of some of our present so-called civilisation. But he did believe that these principles would bring a better time, and that we or our sons might live to see it, and in England; but whether so or not, we might depend it would be worked out by some persons in some parts of the world; and he asked all who heard him to believe this, and to work towards it."

Most of the metropolitan journals have written leaders upon this dividend *soirée*. The *Times* says, somewhat fiercely, but not untruly, "We have heard a great deal of co-operation, but it has done as yet very little for the workman as a labourer. It has neither produced better manufactures nor paid the mechanic better wages." This is true to a great extent. Rochdale, though its best co-operators struggled manfully for it, failed to get co-operation carried out in manufacturing. The wages paid in stores are no great things. The situation of workmen under co-operative employers is nothing to boast of as yet. This company of the Greenings has come late in the field, but it has produced some results, which point to better days for industry. Co-operation has not yet done half of what it is already manifestly capable; but this Manchester dividend *soirée* looks like the beginning.

NITRO-GLYCERINE, OR GLONOINE.

Glycerine, the sweet principle of oils, was discovered by Scheele in 1789. In 1847 M. Sobrero effected a chemical alliance between glycerine and nitric acid, the result of bringing the acid and oil together being to produce a highly-powerful explosive called nitro-glycerine, or glonoine, now known by several other names. For some time glonoine seems to have been used almost exclusively as a medicine, and was an especial favourite among the homœopathists. Bearing in mind the more recent exploits of this remarkable preparation, it sounds somewhat anomalous to find it described as "introduced into practice for the relief and cure of those distressing affections popularly known as 'nervous.'" Gunpowder has been taken as a condiment in the absence of salt, and gun-cotton is understood to be an excellent application for wounds: but we would advise our homœopathic amateurs to look narrowly after their globules of glonoine. Since the date of Sobrero's discovery Mr. Alfred Nobel, a Swedish engineer, has taken the new agent in hand and adapted it for blasting purposes. What is the exact nature of the modification thus brought about we have not yet learned. From the beginning nitro-glycerine was a highly explosive article. Whether Mr. Nobel has made it stronger or cheaper we cannot say; but the product appears lately to have borne the name of "Nobel's blasting oil," and in that capacity has been urged upon the notice of the Californian miners and the constructors of railways. In appearance nitro-glycerine is an oily fluid, of a pale yellow tinge, and looks as harmless as if it were merely some odoriferous compound for use on a lady's toilet table. More strangely still, the contact of flame does not necessarily cause the explosion of this powerful preparation. This is so much in its favour; but, on the other hand, it is found to possess an ugly trick of setting fire to itself, or even exploding spontaneously. In fact, its nature does not seem at present to be properly under-

stood, so that when we are conscions of the presence of glonoine oil we scarcely know what to do with it. This was the predicament of the Sydney authorities at the date of the last mail, a consignment of glonoine being expected in the colony, where its arrival was awaited with no little perplexity and alarm. The first recorded disaster with this compound was at New York, some months ago. A box, afterwards believed to contain glonoine, was found to be in flames. It was thrown out of window, and on reaching the pavement exploded with terrific force, doing considerable damage in the neighbourhood. A similar disaster appears to have occurred more recently at Sydney. A "speculative consignment," amounting to about 100 lb. weight of blasting oil, was landed and lodged in a private store. There, on a Sunday afternoon, when no one was in the building, a fearful explosion took place, completely demolishing the stores and damaging many of the adjacent buildings. A Government Commission was appointed to inquire into the affair, and it was decided that the mischief arose from the spontaneous ignition of the aforesaid oil. An occurrence somewhat similar to that at Sydney, but much more dreadful in its effects, took place at San Francisco very recently. Two boxes, "stained with oil," were brought to that city by the Pacific mail steamer. After being taken on shore the case exploded, the neighbourhood was shaken as by an earthquake, and eight human beings were blown into undistinguishable fragments. Nearly a whole block of buildings is said to have been destroyed by this lamentable explosion. But the most terrific illustration of the power possessed by this extraordinary fluid is that which was exhibited in the destruction of the steamer *European*, while unloading at Aspinwall, the Atlantic terminus of the railway which crosses the Isthmus of Panama. The naval court afterwards held on the spot, in accordance with the terms of the Merchant Shipping Act, has traced this disaster to the explosion of seventy cases of glonoine. The effect was frightful. The wharf, 400 feet in length, was obliterated in a moment, a large steamer near at hand was shaken almost to pieces, and scarcely a building in the neighbourhood escaped uninjured. Worse than all, some fifty human beings were instantaneously killed, and it was only by an accident that the loss of life was not still greater. Concerning the power which the merest accident may thus set in exercise, we may remark that glonoine is computed to possess eight times more force than gunpowder, weight for weight, or thirteen times more force, if the comparison be one of bulk. This latter quality renders the new agent peculiarly valuable for blasting purposes, as it saves labour and expense in drilling. Glonoine is also insoluble in water, which renders it specially available for subaqueous explosions; and for all we know it will play an important part in the future of torpedo warfare.

PROFESSOR FAWCETT ON BLINDNESS.

Mr. Fawcett, the blind member for Brighton, was among the speakers at the annual meeting of the Association for Promoting the General Welfare of the Blind, held in London recently. He said that after he was afflicted with blindness, eight years ago, he found that there was a wonderful compensatory power in Nature, and he thought that power would enable him to cling to the same habits, to cherish the same ambition, to indulge the same tastes, and to enjoy the same pleasure as if this affliction had not happened to him. His experience led him to the belief that where a person was afflicted with blindness, the mind became more concentrated, the hearing more acute, the touch more delicate, and, in fact, every other power seemed to acquire new activity. He had never altered his course of reading after his misfortune. He continued from the page of the book at which he left off previous to his getting blind, and enjoyed his old sport of angling as formerly. He enjoyed the grandeur and beauties of Nature as much as ever, and often when in society, when describing some beautiful river, he stopped to think whether he had really seen it, or if it had been described to him. He thought he enjoyed as much happiness as most people, and he believed every blind person would derive equal enjoyment if brought under the same inspiring influences, the same associations, and made to participate as far as possible in the same pleasures which other people enjoyed.

The Halifax Corporation has decided to add another reservoir to the water supply. It will have a capacity of 50,000,000 gallons, and the estimated cost is about £13,000.

The Art of Killing.—"While everything around us," says the *Temps*, "has progressed, the art of killing our fellow-creatures seems alone to have remained immovable during the last century. In the time of Marshal Saxe each man that was killed in battle represented a quantity of bullets equal to his own weight. Notwithstanding the invention of rifled guns, the proportion remains about the same. At Solferino, for example, the Austrians fired 8,400,000 musket shots, while the number of killed among the French was but 2,000, and of the wounded 10,000. Thus a man was hit every 700 shots, and one killed every 4,200."

TIMES OF WANT.

Oh! Mary, they have closed the mill,
The looms are silent now;
And we must stoop with heavy souls
Beneath the rod to bow.
I feel a throbbing in my heart,
A chill within my breast,
And long to lay my weary form
Within the grave to rest.
For life has been a ceaseless strife
With cares that ever grew;
We slaved and starved, and now, alas!
O God! what shall we do?

I've seen thee weep when thou didst think
Thy tears I could not see;
And seen thee put aside thy bread
That baby fed might be.
While oft thou forced a loving smile,
Although thy heart was sore,
And kissed my pale and bloodless cheek,
And bade me grieve no more.
But now thou canst not hide thy tears,
Thy lips, they quiver too,
Thy hand, it trembles in my own—
O God! what shall we do?

Thy fingers, they are thin and worn
With needlework so cheap;
Thy eyes are red, thy brow is cold,
For want of rest and sleep.
Our little infant, fevered, droops,
And soon will be no more—
It had not starved, had I been rich,
But I, alas! am poor.
I wonder if the wealthy great
Would help us if they knew
Our wretched fate. The thought is vain—
O God! what shall we do?

For never shall these lips of mine
A pauper's pittance crave
While I have life, though after death,
I fill a pauper's grave.
My soul grows fierce. Oh! that my voice
Could ring throughout the land,
And breathe the cares, the wants, and fate
Of labour's starving band;
And bid the lords of gold beware,
Lest they like us may sue,
When revolution comes, and cry,
O God! what shall we do?

—"*Songs of Labour.*" *By John Plummer.*

THE NEW STEEL FOR ORDNANCE GUN BARRELS AND TUBES.

At the present period, when, whether with reference to Krupp's cast steel, or Armstrong's elaborately-wrought guns, experiments with heavy ordnance have been conspicuous failures, it is in every respect satisfactory to be able to draw attention to a process of working steel which promises results of the most important character. Thanks to Mr. Bessemer, steel is produced at this day in quantities and in a state which encourage further efforts of industry contemporaneously with a demand for the metal in a condition of the highest possible excellency, more pressing than was ever before known. A process has just been developed in South Staffordshire which is calculated, by a thorough manipulation, to secure from the metal the maximum of strength. The patentees take Bessemer ingots and reheat them. They then not only hammer them right and left, but they do that which hammering on the surface can never accomplish. To form a cylinder, either for a heavy gun or a light rifle, the centre of the mass that has been previously worked under the hammer is condensed by the use of a punch, which is made to move radially from a point equidistant from the extremity. A mandrel is then inserted into this partly-formed mould, and it is further elongated by being passed through rolls, thereby to still more greatly improve the quality of the metal, and to impart to the mould a mathematical accuracy of dimensions, alike internally and externally. Thus six times the amount of work has been put upon the steel than would be possible by any other process; and thereby the maximum of strength has been secured, and a solid tube produced, which must of necessity possess greater strength than any obtained by processes less exhaustive of manipulative operations. John Brown and Company, of Sheffield, have recently been making experiments with the process. The result of these experiments has been that they have succeeded in obtaining the licence for manufacture in this country from the patentees; and they are now engaged in making most ample preparations, with a view to the production of tubes for seven-inch ordnance, hollow, marine, and other shafting, railway axles, locomotive marine tubes, projectiles, and the like. So far as the process relates to the making of gun barrels, it is undoubtedly a great success. The patentees are now rolling gun barrels produced by this method, which have been pronounced superior to any ever before offered to the trade by nine of the first gunmaking firms in Birmingham, to whom they are exclusively supplied in this district. Other, and even more valuable, testimony to the worth of such barrels has been forwarded to the patentees from foreign armouries. We may state that the patentees have taken the requisite steps for securing their invention in the leading countries of the world.

ENGLISH WORK-ROOMS.

The majority of work-rooms are mere lurking-holes of burrowing disease. Not long since, impelled at once by interest and curiosity, I looked into a sort of den behind the shop of a London tailor. In this hole, for it was indeed no more, a number of men, with barely room to ply their implements, sat elbow to elbow and knee to knee. The industrious and respectable employer spent his days betwixt shop and workshop. Only forty, and yet seized with all-devouring phthisis, he is now at rest. Such is the cupidity of some, coupled with the unrelaxing exigencies of trade, that nothing short of the life and marrow of humanity will satisfy them. People adore an idol of more hideous attributes than any worshipped by the New Zealander or yellow Fiji. So feeble becomes the respiration in multitudes of over-tasked, under-fed workmen and workwomen, poor exhausted fragile creatures, condemned habitually to breathe air laden with filthy, irrespirable matters, that they seem hardly able to speak or breathe. Compare, only compare, with such a group of hodmen or labourers, a bevy of rosy, deep-chested Cornish or Scottish fisher-girls. Ah! how great, how immense is the difference! The sonorous period, the lusty carol, rolls without an effort from their lips. They hardly seem of a like race. Yet such as they, and better still than they, might all other men, all other women become.—*MacCormac on Consumption.*

A MODEL STATE.

The great part which the State of Massachusetts has played in the war for the American Union, and the disproportion between the magnitude and population of that State and its influence in the council and action of the whole nation, together with the causes of that influence, form the leading topic in Consul Lonsada's annual report from Boston for the year 1865. All the States of the American Union are self-governing commonwealths—masters of their own actions save as to their federal liabilities; but Massachusetts has always displayed a very marked character of its own. Its area is but 1-376ths of that of the Union, and its population 1,250,000, or only 1-30th of that of the United States. The lead which it has acquired with these slender advantages is due to its enormous moral, intellectual, industrial, and commercial activity. No State contains a greater proportion of cultivated land. Her revenue from agriculture may be put down in round numbers at 25,000,000, and that from manufactures at 150,000,000, irrespective of the extraordinary increase during the war. Her principal port of Boston, admirably screened by islands (now heavily fortified) against the storms of the Atlantic, is accessible to the largest vessels, and her ships, in spite of the small extent of her shore, amount to over 800,000 tons. The ships of all France, with her 600 leagues of coast, hardly exceed this measurement. Her fleet for the whale fishery, chiefly from the port of New Bedford, reaches 150,000 tons, whilst the the rest of the Union barely furnishes 14,000 tons. The great proportion of the United States shipbuilding takes place within her ports, and the year 1865 alone added nearly 100,000 tons to the stock already existing. Amongst her products acknowledged to be the best, and everywhere sought after, are agricultural implements, carriages, harness, sewing machines, and general machinery. Boston itself is a marvel of industry and opulence. Places at which, five years since, vessels were unloading, have been filled up, and a series of palatial mansions and elegant streets occupy the ground. The banks employ a capital of 75,000,000 dollars, and the deposits in 1865, as returned by the savings banks, exceeded 65,000,000 dollars, with the cost of management not exceeding one-third of 1 per cent. per annum, being 20 per cent. less than the cost of managing similar institutions in England, while they are yielding a much larger income.

Many of the manufactures of Massachusetts flourish in virtue of the protection they receive under the customs tariff—in other words, at the expense of the consumer, who is artificially excluded from the best market. But there are others, the prosperity of which rests on the soundest basis, on superiority of manufacturing skill, so incontestable that they successfully enter the foreign market.

Mr. Lousada observes that, "Some of the higher branches of art are successfully competing with foreign importations, such as lawns, ribbons, serges, the more delicate and costly fabrics of wool, cutlery, watches, plate-glass, plated ware, and horse-shoes and horse-shoe nails by machinery. The whipple file, also made by machinery, is a perfect article, and has superseded the English file made by hand. Spool cotton, which was, prior to the war, wholly imported from England, has now found a rival in the Hadley Company at Holyoke, which is eminently successful. The American Watch Company at Waltham, a few miles from Boston, furnish watches, under duties of 10 and 20 per cent., which supply one-sixth of the entire demand of the whole

country, whilst the higher grades rival in quality the best watches of England, and have driven most of them from the market, and met them in successful rivalry in Canada; indeed, the managers boast that, were the home demand not so great, they would be ready to meet English watches in London itself. They are independent of duties. At Springfield, in this State, the manufacture of rifles is well known: it has been carried to 1,000 a day: and the Spencer rifle of Boston—which proved to be the best weapon of the war—has been conducted on a large scale. I may mention incidentally of this weapon that it is loaded with seven cartridges at the breach, is discharged seven times in eleven seconds, and reloaded with seven charges in less time than a common rifle. On trial, it has missed but once in 1,500 times, and it carries a ball accurately 2,000 yards. There are also large foundries at South Boston devoted to casting 8, 10, and 15-inch cannon and Schenkle shell."

Considering that the ever-ready explanation of American prosperity—land for nothing—cannot be offered to account for the welfare of the people of Massachusetts, what shall we say to the following statement?—"Every one from Europe must be struck by the total absence of mendicity in the New England States, and by the exceedingly comfortable clothing that the whole population seem to wear, and it speaks volumes for the government, the education, the employment, and the nourishment of the families in Massachusetts, that less than 1 per cent. of the inhabitants in 1865 were either idiots, deaf and dumb, insane, blind, paupers, or convicts."

Mr. Lousada remarks that there are one or two institutions in Massachusetts which must strike every observant foreigner with admiration. For instance, the inimitable arrangements for public education, by which every family can educate their children almost free of cost; the public libraries, which, in addition to their ample and stately rooms for readers, lend out without charge any of their volumes, and, to the honour of the people, it should be stated that the loss last year on 185,000 books lent for home use was less than one-fourth of 1 per cent. The charities are large and well organised, printed returns being annually published and distributed of all their accounts; and, indeed, the whole of the municipal and state expenditure to the smallest items is also printed, and a copy left at each house, so that a complete popular control exists over any abuse. Owing either to chance, or to the fact that from her wealth Massachusetts has more leisure for study and the fine arts, it is a notorious fact that almost all of the leading minds, acknowledged as such by the whole United States, are natives and inhabitants of this small State, and consequently her influence in the council of the nation is out of all proportion to her territory.

"S. G. O." ON THE EDUCATION OF THE WORKING CLASSES.

At the meeting of the Yorkshire Union of Mechanics' Institutes, at Halifax, the Rev. Lord Sydney Godolphin Osborne—"S. G. O." of the *Times*—delivered an eloquent speech. He said he recollected the day when he was called names, which he might term scurrilous, for suggesting for the benefit of the working classes only one-fiftieth part of what had been said at that day's conference, but that day had gone by. What was now the public opinion respecting the class of whom it was said that education would make them discontented workmen, disloyal subjects, and sceptics in religion? Why, of all the public pets that existed at this moment, they were the greatest. No matter on what side of the House an hon. member might sit, no matter what publication one took up, the working man was the universal pet, however much gentlemen might differ as to how that pet should be treated. The friends of education used to be told that if they went on at the pace they desired, they would make the working man a politician, a student of newspapers, that he would consider himself enabled to give an opinion upon great national political subjects, and aspire to a higher condition than became him; that he would become conceited, discontented, and independent, rather than humble, subservient, and content to go through life still serving—still keeping the same station—a man who lived and died in the same harness, and left children to be yoked to the same work and to the same end. But, after all, how had it proved to be? What was the true touchstone of the conduct of the working men in this country? In days when they were called the "dangerous class"—in days of political agitation or commercial panic, when the distant sound of war seemed almost to roll within one's ears—in days of bitter polemical controversy—the first question was "How will it be if these opinions get loose in the manufacturing districts?" Well, they had got loose, and who was going to tie them up again? Who was going to check the power of the press, or close the door of the reading-room, to forbid the working man considering political subjects? No power could do it, and no one desired it. He could recollect the time when it was said that the working men, of all others, were the greatest dupes of orators—that flatter them, and speak to them of schemes of promotion to heights that they could never be raised to, and a person would gain their sympathy; that they were the most readily duped by what the Americans call "stump oratory;" that of all classes they were the easiest to be led away by fluent speaking, and by appealing to their passions and ignorance. But what was the state of things now? Had such oratory, or the political agitation of the last six or eight weeks, or the effects of such speeches as those of Mr. Gladstone and Mr. Bright, raised one discontented or turbulent spirit? In his younger days it used to be "the dangerous classes of the manufacturing districts," the days of the yeomanry, of special Cabinet Councils, and of fears in Cabinets of those "dangerous working men." But had there, during the late proceedings in Parliament, or during the recent commercial panic, been one single moment of anxiety on the part of the ministers with respect to those "dangerous classes in the North?" Some social, political, and religious knowledge was now at the command of the great mass of the working men; it was at a price within their reach; and, if Mechanics' Institutes were to be closed to-morrow, the tide of intelligence would still flow on. He was at a loss to foresee what would be the result of that high flood; higher powers than theirs would direct it, and it would be enough for them to see that no man should be left in ignorance except through his own neglect. Even at the risk of making the working man a politician, or a divine, or a theologian, or a sharp, clever criticiser of things around him, they were still bound to go on with his education. He would allude to one most delicate question which it might, perhaps, be wiser for him to avoid. For years past his attention had been drawn to the gradual combination of working men into distinct class interests. In the working of their great benefit societies, in the management of their admirable co-operative and building societies, and in no end of social matters, he could see that labour was coming to be considered by those who possessed its power as capital which, in their own interest, they had, like any other man in a free country, a right to increase by any legitimate object, or by any honest and fair means. The vast improvements in our machinery were the world's wonder, and none would deny that they had not yielded great returns for the capital that had been spent on them; the country teemed with proofs of it. Did those great improvements in mere dead plant call for no increase in the skill of him who waited for it? If our means had been increased by the improvement of machinery upon which our operatives waited, let us sympathise with those operatives, should they get a little importance in seeing that their own increase of skill had not met with that increased reward which they might think they were justly entitled to. He believed that when the day came when some happy compromise between capital of mere wealth and capital of mechanical labour should have been arrived at, the manufacturer would really gain, while the condition of the working man would be very much improved. Would the skilled mechanics of the present day be content to go back in the scale of figures? No; and if the present Saturday half-holiday movement was granted in London, would not the mechanics put forth the greater amount of skill and energy which that holiday would afford to him, in order still further to increase his social position, and to elevate himself in society? He believed that in the constant trade disputes that were happening, if, instead of pressure from the one side or pressure from the other, the real friend of the working man would tell him the effect of those proceedings without flattering his prejudices—tell him truths that would be good for him—he believed that those true friends would be met by those men in a spirit that would soon put an end to many of those social disturbances that at present destroyed the just claims of capital, and injured the claims of the capital of labour. He believed that many of the more respectable mechanics were in a far happier condition than some of those around them who seemed to be rolling in wealth; but, taken as a class, he did not believe that, as a whole, the working men were any better or any worse than any other class. He would not magnify the position of one by detracting from the other; and there were in that town especially abundant proofs that masters were not forgetful of their duty. The progress and object of those institutions must be still further to raise the condition of the working man. The whole course of modern legislation was tending in his favour; no party could hold governmental power who would ignore him; and, on the other hand, he hoped he should never see a Government nor a House of Commons that would suffer the whole combined power of the working classes to do one single act of tyranny against a master.

Things Talked About.

We have received from Brisbane, Queensland, the report of a rather remarkable celebration. Two years ago the eight hours system was generally adopted; and on the 15th of March last the second annual celebration of the success of the movement took place. There was a procession of the various trades. The *Brisbane Courier* tells us that "the procession marched in remarkably good order. The tradesmen were preceded by Seal's band, which was engaged for the day. The order of march was the following:—First, there were the masons, wearing a blue ribbon, and carrying their banner of last year. Their motto was, 'Union is strength.' The masons numbered about sixty. The next were the bricklayers, to the number of about 120; their colours were red, white, and blue. The third order was the carpenters, and the banner they carried was specially prepared for the occasion. It is a very handsome one; the emblems of the trade are painted on it in gold letters, and there is also the motto, 'United we stand: divided we fall,' on a crest supported at each side by the figures of a man. The cost of the banner was £40. Their colours were pink and white, and they equalled the bricklayers in number. The fourth body comprised the painters, of whom there were about twenty; colours, green and white. Their banner was a new one, and the motto was, 'Let Brisbane flourish.' Last, came the plasterers, mechanics, and others, in a body consisting of about 150." A steamer had been chartered, and about 400 excursionists, including the wives and children of the men, made a trip to Lytton, a picturesque spot on the shore of the river, where numerous parties were soon formed for various games, dancing, and short trips in sailing boats. In the evening there was a special performance at the theatre, and short addresses were delivered. The committee were able to "point with pride to the number of artisans who are members of the School of Arts, in Queen Street; of the Mechanics' Institutes of South Brisbane and Spring Hill, who devote their surplus time to study; and they assert, without fear of contradiction, that among the artisans of Brisbane are to be found men of talent equal to any who sit in the senate, or those who manage or mismanage affairs in the town council. This advance in the social scale they in a great measure ascribe to the influence of the eight hours system, which, while lessening the hours of labour, gives the artisan greater opportunities for study, of mixing with his family, and encircling himself with domestic ties; thus, in the end, rendering him a better citizen, a better husband, and a better father." A little amusement was created by an address to the ladies of a very gallant character:—"The working men desire to say that, though the hours of labour are necessarily limited to an employer, they have great pleasure in placing the remainder of their time at your service unconditionally."

The growing disposition among the working classes to enjoy their few holidays wisely, and to seize the occasion of visiting places where the mind may gain something as well as the body, is shown in the fact that on Whit-Monday 36,573 persons visited the Zoological Gardens, being the largest number ever admitted on any one day since the gardens were opened to the public. A visitor who enjoyed ample means of observation says, "In this vast concourse of persons, many of whom evidently belonged to the ranks of those who labour hardest for their daily bread, no case of misbehaviour occurred, nor was any injury done to the society's valuable collection of animals." On that same day the British Museum, the Crystal Palace, the Gardens at Kew, the Parks, and every other place of popular resort for recreation was equally well attended; and the police records are actually silent as to any charges of misbehaviour—a splendid testimony to the temperance, good temper, orderly spirit, and real respectability of the working classes of the metropolis.

Losses of life on railways are increasing, not among passengers, but among those men who are servants of the companies. We can scarcely avoid the conclusion that most reprehensible carelessness is displayed by traffic managers, inspectors, and other superior officials, in not adopting some efficient means of protecting porters, platelayers, and others engaged in necessary and most arduous duties. This is not the first time we have alluded to the subject, and we recur to it because numerous fresh instances are recorded in the newspapers. In one case the coroner's jury made a special addition to their verdict. A gang of platelayers were employed in levelling some ballast near the Ludgate station of the London, Chatham, and Dover Railway. While so employed a train approached, and knocked down one poor fellow, who was so frightfully injured that he died in the hospital a few days afterwards. One of the platelayers said, in his evidence, "We have thought of having a man on the look-out, *but we are not allowed to think.*" If a man were kept specially on the look-out, accidents would be prevented. The jury said, in their verdict, "The London, Chatham, and Dover Railway Company ought to have men placed on the look-out while the lives of the workmen on the line are in jeopardy." The public quite agree with the jury on this subject. Men employed on railway work are something more valuable than mere rolling stock.

A somewhat similar tragedy, but even more terrible in its character, occurred in the tunnel of the Metropolitan Railway, near King's Cross. Some platelayers were at work, when two broad-gauge trains (both gauges are laid on the line) were seen approaching in opposite directions. The men, on the alarm being given, threw themselves down, because the distance between the two broad-gauge carriages, when abreast, was, in the six foot, about two feet; but when the men lay down they were supposed to be below the level of the carriage steps, where the distance between the wheels of the two trains was six feet. They were not quick enough. One man, named Winstone, was caught in the wheels of one of the engines, and when it emerged from the tunnel his mangled body, a mass of pulp and blood, was whirling round

with the wheels. Three other men were most seriously injured. The traffic manager endeavoured to show that precautions for safety were adopted; but Dr. Lankester, the coroner, shrewdly remarked that, if that were the case, it was certainly remarkable that four men should have been injured. The jury thought so too, resolved on examining into the matter more closely, and adjourned the inquiry. On the South-Eastern Railway, near Paddock Wood, a platelayer has been decapitated. He was engaged on the line when an engine knocked him down and killed him in an instant. Here, too, it would seem that a great want of proper care was displayed. Sometimes, it must be admitted, fatal consequences arise from the men's own carelessness and indifference to danger, and sometimes from the neglect of their fellow-workmen and signalmen. A young man, an engine-cleaner, has been killed near Reading in consequence of walking along the line as a short cut to the engine-house; and a collision on the North London Railway, at the Shoreditch station, by which an engine-driver was killed, was due to the mistake of a signalman, who had signalled "all clear." He will have to answer at the Old Bailey for his neglect; and if others in a higher position had also to answer charges of "manslaughter," perhaps the expense of keeping a man on the watch would not be objected to.

Depositors in Post-office Savings Banks who may have felt a little puzzled over the proposed appropriation of their deposits to pay off a portion of the National Debt should procure, for a few pence, at the Queen's printers, a return explaining Mr. Gladstone's scheme. They will see that there is not the faintest foundation for any alarm in the matter. Their money will be forthcoming when wanted, and the interest too, and yet a large amount of our national burden will be wiped off. Strange, yet true!

If ever a body of men had a claim upon our sympathy when asking for a reduction of the hours of labour, the journeymen bakers are those men. We hope they will not be left to their own necessarily limited resources in fighting the battle. Money, time, and talent may honourably be devoted to their assistance. At a meeting held a few days since they resolved—"That, in the opinion of this meeting, night-work and the unlimited hours of labour for a fixed remuneration are opposed to the physical, moral, and social interests of the trade, and totally inconsistent with the spirit of the age in which we live; it therefore pledges itself to do all in its power to organise the trade in London, so that on an early day a demand be made upon the employers of labour for altering the system of work in the baking trade, and that the hours for working be fixed from five o'clock in the morning until five o'clock in the afternoon."

From all quarters comes the news of continued and fresh strikes. The men employed in the stables of the Manchester Omnibus Company have struck for an advance of wages, and we regret to say that some violence has been displayed, the perpetrators of which have been fined by the magistrates. The carters of the same town are agitating for short time, and wish to leave off collecting goods after six o'clock in the evening. It is stated that the carters cannot reckon on reaching home for four hours after leaving the warehouse door; and whatever time they cease work at night, they must be at the stables at half-past five o'clock in the morning.

The master engineers and shipbuilders on the Clyde have resolved on a thorough lock-out. This determination, which, they say, has been provoked by the continued demands of the men, may be the beginning of a terrible struggle.

We are pleased to see it announced that the masons' strike in Bristol has terminated, the masters having acceded to the demands of the men.

The rumours of war on the Continent, and the consequent uncertainty of all industrial occupations, are beginning to be sorely felt. The operative classes in Prussia, especially, are ardent advocates of peace, and would resist, heart and soul, if they dared, the demand upon them for military service which is tearing them from their industrial pursuits and converting them into soldiers, while their families are left to perish.

"S. G. O.," by which initials the Rev. Lord Sydney Godolphin Osborne is best known to the public, has made an admirable speech at Halifax, on the occasion of the celebration of the twenty-ninth anniversary of the Yorkshire Union of Mechanics' Institutes. We give the substance of the speech in another column. It will bear reading more than once, and deserves the closest attention of those to whom it was addressed. "S. G. O." never flatters, and never hesitates to point out a defect when he sees one, or enforce a truth when a truth is needed.

Bolton has been enriched, during the past week, by the gift of a public park and a recreation-ground. The park, which is about forty-six acres in extent, has been established under the provisions of the "Public Works Act," and is situated on the Chorley New Road, one of the pleasantest suburbs of Bolton. The recreation-ground is the gift of Alderman Robert Heywood, of Bolton, and is named after him. The occasion was celebrated by a banquet in the evening, after the opening ceremonies had been duly performed, and among the guests were the Earl of Bradford, Mr. W. Gray, M.P., and the Mayors of Manchester, Salford, Burnley, Oldham, and Preston.

Co-operative Intelligence.

Oldham Building and Manufacturing Company, Limited.—This association is composed of working men, to the number of 1,200 shareholders. The shares are £5 each. The company's capital in 1860 was £2,000; this March quarter, 1866, it is £93,000, including loans, which are principally lent by the shareholders. In their last report the directors state, after having allowed £460 0s. 9d. for the reduction of doubtful accounts, there is a balance from trade of £1,180 7s. 11d., which, after paying £512 4s. 4d. for loan interest, leaves £668 3s. 7d. to the credit of profit and loss account, the balance of which now stands at £7,656 9s. 10d. During the quarter considerable progress has been made towards filling the mill with machinery; 44 cards, 50,000 mule spindles, and three pairs of twiners, containing 4,524 spindles, being now at work. An additional steam boiler has been put down, which completes the steam power for the present mill.

Leicester.—The twenty-second quarterly report of the Leicester and Leicestershire Industrial Provident Society, Limited, states that continued prosperity attends their efforts. Their numbers have increased during the quarter by the addition of thirty-three new members. After paying all expenses of management, and 6d. in the pound on *non*-members' purchases, they have realised a net surplus of £73, which will afford a dividend of 1s. in the pound on the members' purchases. The cash account shows the receipts during the quarter to be £1,397 3s. 10d.

The Sheffield Improved Provident Co-operative and Industrial Society, Limited.—The first annual balance-sheet and general statement of the transactions of the society for the past twelve months shows the amount of cash receipts for goods sold, £2,417 15s. 2d., and a net profit (after allowing interest at the rate of 5 per cent. on all paid-up shares, reduction on the fixed stock, commencing the second half-year, at the rate of 5 per cent.) of £82 7s. 6d., in the disposal of which the committee recommended £5 to be laid aside to start a reserve fund; 6d. on the pound for non-members' purchases; 7d. for the first, and 1s. 3d. for the second half-years on members' purchases; leaving a balance of £9 4s. 4d. to meet outstanding cheques.

Clitheroe Equitable Co-operative Industrial Society, Limited.—At a recent meeting of this association, Mr. Richard Aspden, the secretary, presented a report of the rise, present state, and prospects of the society, from which it appeared the society was established four years ago. At the end of the first year its capital amounted to £572 15s. 11d.; goods sold, £3,131 14s. 6½d.; profit, £173 5s. 4½d. The second year, capital, £659 6s. 2d.; goods sold, £3,499 16s. 10d.; profits, £217 2s. 6¾d. The third year, capital, £1,258 5s. 11½d.; goods sold, £4,707 3s. 5d.; profits, £325 4s. 5d. The fourth year, capital, £1,411 14s. 5d.; goods sold, £4,426 12s. 8d.; profits, £261 3s. 4d. There had been a steady accession of members, the present number being 250.

General Information.

CLUBS AND INSTITUTES.

METROPOLITAN DISTRICT ASSOCIATION OF WORKING MEN'S CLUBS AND INSTITUTES.

The committee for organising this association met again on Monday evening, the 14th ult., at the offices of the parent society, 150, Strand, and finally agreed to the following statement of objects, rules, &c., which we give entire, as they may be useful to other district associations:—

"Objects.

"The objects contemplated by this association are:—1. To promote the success of the London Working Men's Clubs and Institutes by co-operation and the cultivation of a brotherly spirit. 2. To make each of them a centre of increased usefulness and good-fellowship. And, 3. To develop the growth of the Club and Institute movement generally in the metropolis.

"Modes of Operation.

"The following are some of the modes in which it is proposed to carry out the above objects:—

"1st. By an interchange of friendly visits between the members of the different clubs, such visits being arranged previously by the committees.

"2nd. By the co-operation of clubs, situated sufficiently near each other, for the establishment of classes, the delivery of lectures, or the holding of elocutionary, musical, and other entertainments.

"3rd. By the arrangement of meetings for social amusement and joint discussions; also for chess, cricket, foot-ball, gymnastic, and other matches; and for competition in recitations, essays, and poetic composition.

"4th. By the interchange of books, scientific and musical instruments, diagrams, and works of art.

"5th. By arranging for flower shows and exhibitions of art and industry at the clubs, as well as for joint excursions, &c.

"Agency.

"A committee, consisting of representatives from each club and institute in union with the association, and of such other persons as they may invite to act with them.

"Rules.

"1. The Committee of the Metropolitan Association of Working Men's Clubs and Institutes shall meet on the second and fourth Friday in each month for the transaction of business, or at such other times, and at such hours, as they may decide on.

"2. At such meetings, the members present shall appoint one of their number to act as chairman of the meeting.

"3. The committee shall appoint a secretary to the association, who shall keep the minutes of their proceedings, conduct the correspondence, and transact the business of the association generally.

"4. The committee shall appoint a treasurer of the association.

"5. Every metropolitan club and institute desiring to be united with the association shall be admitted on the payment of an annual contribution of 5s. to the funds of the association, or such other sum as the committee may from time to time determine, for the purpose of defraying printing, postage, and similar expenditure.

"6. The meetings of the committee shall, with the permission of the council, be held at the offices of the Working Men's Club and Institute Union, or wherever the committee may at any time appoint.

"7. Each representative of a club attending the meetings of the association shall be furnished with the credentials of his appointment by the committee of his club.

"8. Every club in union with the association shall have the power of sending two representatives to the meetings of the committee.

"9. The association shall not in any way interfere with the *independent management* of the clubs in union.

"10. Any club and institute which shall not pay the fee referred to in Rule 5 within one fortnight after the date on which it falls due, or shall not send a representative to the meetings of the association for three months running, shall not be considered to be in union.

"11. It shall be in the power of the committee to add to or to alter these rules from time to time, a fortnight's notice having been previously given of any proposed addition or alteration, by the issue of a circular to all the clubs and institutes in union with the association."

The next meeting of delegates from those London clubs, which may be desirous of enjoying the advantages afforded by friendly co-operation, is to be held

On Friday, the 8th of June, at 150, Strand.*

Tea on the table at seven o'clock; business commences at eight, when A. H. Layard, Esq., M.P., is again expected to preside. The managers and members of clubs are particularly requested to notice the 9th Rule, and to understand that no interference with the individual action and finances of associated clubs is in the slightest degree contemplated by this organisation. It is believed that club committees and secretaries will derive substantial and increasing benefits from the plans for joint action and co-operation now proposed. Mr. Pocklington, the District visiting agent employed by the union, has been appointed honorary secretary to the District Association. Let me earnestly beg the managers of all Working Men's Clubs and Institutes, whether in London or the country, to use every effort for promoting associated action between such of these societies as are sufficiently near in any given district to admit of it. I was greatly in hopes that, as a result of various visits I made the latter part of last year, there would have been district unions of clubs formed in Hampshire and Sussex, Lancashire and Cheshire, Yorkshire, Northumberland and Durham; but at present, the friends who undertook the organisation in each case have proved something like broken reeds. Doubtless, they are all so active and useful already, that their acquaintances leave them no time to carry on other useful enterprises; but then they should find efficient coadjutors or substitutes. Somebody says that this is the secret of all successful "administration."

I should be most happy to furnish any person, applying to me, with printed suggestions both for the plan and objects of the district co-operation which we desire and recommend.—Henry Solly.

150, Strand.

Hope on, Hope Ever!—Most folks are the better for a little encouragement now and then; and we are all of us, I suppose, apt sometimes to grow weary in well-doing. Hence the value of mentioning facts which occur occasionally, showing the value of good men's work, perhaps of good done when the doer had nothing but a dismal conviction on his mind of having utterly failed. My esteemed friend, the chairman of the Executive Committee of our Union, laboured long to maintain in useful existence a Working Men's Club in Brighton, intended especially for that much-tempted and useful class of men yclept flymen and wheel-chairmen. All his efforts, however, proved unavailing, though he aimed especially at making the men feel it was *their* club, and at interesting them individually in its manage-

* This will be instead of the Tea Meeting of Secretaries, hitherto held on the last Thursday in the month.

ment and working. After having spent a large sum of money upon it, he was obliged at last to withdraw his support, and it was closed, most of the members having manifested a culpable degree of indifference, and, I must say, of what seemed like ingratitude. A few days ago, however, Mr. Pratt received the following note, which doubtless illustrates what others have experienced, though they may not have told or written their experience, as this man has happily done, for the encouragement and reward of a benefactor.—Henry Solly.

"3, Cavendish Street, Brighton,
16*th May*, 1866.

"To Hodgson Pratt, Esq.

"Dear Sir,—Just as I had posted my letter to you yesterday, a little incident occurred that I thought would be encouraging to the council of the Club and Institute Union, if at any time they should feel desponding of the work they have taken in hand. I had just commenced to wash my fly when one of our old members of the Flymen's Club came into the yard. I dare say you will remember him: he was a tall man, with hair and whiskers turning grey. He was a constant attendant at the latter part of our existence as a club, and a very attentive listener at the lectures and readings. His name is C—— P——, a hand-chairman. I said to him, 'I have just posted a letter to an old friend of ours, Charles—to Mr. Hodgson Pratt.' 'An old friend of mine, you may well say,' said he; and placing his mouth to my ear, he whispered, 'If it had not been for Mr. Pratt, I should not have had a penny in my pocket; but, thank God, I have now £10 I can call my own.' 'Ah!' I said, 'Charles, how was that?' He said, 'You recollect when Mr. Pratt came forward and took the responsibility of our club on his own shoulders when it was about to be broken up? Well, I had not a penny in my pocket, and nowhere to go to but the public-house. I did not know the value of workmen's clubs then; and, bad as I may be now, what little of good there may be in me now, I date it all from that time.' I replied, 'I suppose you belong to Windsor Street Club now, Charles?' 'Yes,' he said; 'you know the time of the year is now coming on when I shall not be able to attend the club, but I shall continue to pay, for I have felt the advantage myself, and I will do what I can to assist others to do so too.' It did appear to me at the time so like a realisation of the passage from the old Book of Books—'like bread cast upon the waters, it shall be seen again after many days'—that I could not refrain from troubling you with the account of the circumstance. Hoping I have not trespassed on your valuable time by doing so, I remain, faithfully yours, "Joseph Wood, Flyman."

Taunton.—The third annual meeting of the Taunton Working Men's Association was held on the 17th instant. The committee in their report "regret that so few comparatively of the working men of Taunton seem to appreciate the great privileges afforded by the Association; but hope that when the character and variety of the large collection of new books recently added to the library become known, together with the list of newspapers and periodicals always supplied in the reading-rooms, the artisans will enrol themselves in greater numbers, and manifest a deeper interest in an institution specially formed and sustained for their benefit." They reported "that the net proceeds of the Industrial Exhibition which had been promoted and carried out by the members of the Association was £40 5s." The expenditure for the past year had been £53 7s. 0½d., the receipts £77 16s. 10d., leaving a balance in hand of £24 9s. 9½d. T. Meyler, Esq., was re-elected president; the Rev. W. A. Jones, M.A., was elected treasurer; and Mr. H. A. Hammett was re-elected as secretary for the ensning year.

Correspondence.

**** We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* Working Man, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*

We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

MR. MAURICE'S MEANING.

To the Editor of the Working Man.

Dear Sir,—Your reviewer of Dr. Maurice's book, entitled the "Workman and the Franchise," would no doubt be able to answer for himself; but if you think it useful, a few words might be said in your correspondence columns in reply of Mr. Rossiter's letter. I had not the happiness, like him, of hearing Mr. Maurice's lectures when delivered at the Working Men's College. I should think it probable that the reviewer never thought of what Mr. Rossiter calls the "oft-recurring complaint that Mr. Maurice is too indefinite in the statement of his opinions." Reading that book on the Franchise, he would concern himself merely with the impressions which the book gave. Anyhow, I, as one who have read the book with a very anxious desire to learn Mr. Maurice's opinions, have felt regret that his own conclusions were not distinctly expressed. Considering upon how many and how lofty subjects Mr. Maurice has written, any one reader must have very wide knowledge indeed to be able so accurately to judge him as to say where he has or where he has not fallen short of "definiteness." I pretend only to give an opinion upon the book now in question. I am thankful for it as it is. It is a distinct contribution to the discussion of the subject—as far as it goes it is good. I should say with the reviewer, that it is a wholesome book; yet, a book which is good as far as it goes, might be still better if it went farther. It arouses curiosity as to what the author thinks, but does not satisfy it. Mr. Rossiter says, "Any one who can follow Mr. Maurice's train of thought, will not, I think, often fail to find a very definite meaning clearly expressed." Does Mr. Rossiter know that nothing is more uncertain than the interpretation of the meaning of an author who does not himself formally express it? Mr. Rossiter admits that the reader may sometimes, though "not often," fail to discern it. Why should the reader be left to fail at all, when the author, by a few words, can save him from that disaster? Mr. Rossiter says, "The reader may find" (in the majority of instances) "a very definite meaning clearly expressed." Now, what is it? Can Mr. Rossiter tell us? A reader may think he knows his author's meaning; but if the author is silent, who is to assure him that he does know it—that he has not failed, and made no mistake? Mr. Rossiter says that Mr. Maurice's "modesty, or his charity, or both combined, prevent him from speaking *ex cathedrâ*." It may be "modesty," but I do not see how it is "charity," to withhold a dogmatic opinion which the reader seeks and desires, and would profit by. The readers who want to know a writer's opinion are commonly persons who can profit by it without their independence of judgment being destroyed. I like authors who are dogmatic. I like authors who, having great opinions, authoritatively avow them. There are authors whom I have the misfortune to read whose opinions I don't want to know, and I am grateful to their "modesty, or their charity, or both combined," when they withhold them. I see quite enough of their capacities of thought not to have the slightest interest or curiosity in knowing what their definite opinions are. But Mr. Maurice is a thinker, and I want to know what *he* thinks. On the question of the franchise he has a right to speak "*ex cathedrâ*," and I wish he would do it.

Mr. Rossiter is not only a pleasant, but a suggestive correspondent; and, if he is of opinion, as he declares he is, that any one may (in most cases) find a "very definite and very clearly-expressed meaning" in Mr. Maurice's book, Mr. Rossiter must have found it, or he could not say so much. Will he, therefore, confer upon many readers less fortunate, the favour of telling us what it is? Mr. Maurice's subject is "The Workman and the Franchise." Now, the questions arise, Upon whom should the right of the suffrage be conferred?—upon all workmen?—and upon workmen only? Is Mr. Maurice in favour of universal suffrage? If so, should women be included in it?—and if not, why not? Should intelligence or property give the right to vote? Should it depend upon industry or intelligence?—or both? If upon intelligence, what kind?—and how should it be ascertained? Mr. Rossiter says Mr. Maurice is not a "legislator;" he is a "philosopher." Then he is philosopher enough to explain what he has written about. If Mr. Maurice is not "legislator" enough to have definite opinions upon these points, how can workmen, whom Mr. Maurice addresses, pretend to have them? Mr. Rossiter tells us Mr. Maurice is a "historian." Then he knows the history of this question. He has formed opinions to no practical purpose unless he sees how they are to be realised. And the working man prates like a child, and no politician regards him, unless he can say what he wants, can show that it is practicable, and can explain how it is practicable. No one knows better than Mr. Maurice how that statesmen in these days (if we except Mr. Gladstone) never take any initiative. Their great policy is to do nothing, and to give good reasons for doing it. All their genius lies in letting things alone; and nothing pleases them better than to deal with men who think they know what they want, but have never thought how they are to get it, and who are unprepared with any answer if the question is put to them.

I am ashamed to write so long a letter in answer to Mr. Rossiter's short one, but this gentleman owes it to the candour of his own admission. The lawyers say they can hang anybody if they can but get a scrap of written paper from him. I have no wish to hang Mr. Rossiter, but we have got his scrap of paper, and on it is written the declaration that Mr. Maurice's meaning is definitely and clearly ascertainable in his book. He who says this must know what the meaning is, or he could not have said so much. I therefore pray Mr. Rossiter to write again, and tell us what it is, on the essential points I have named—the want of information upon which seemed to me to constitute the reviewer's difficulty. Anyhow, they are mine.—I am, &c., One who Wants to Know.

TO CORRESPONDENTS.

Thomas Evans.—Macmillan and Co., London.

W. W.—Your queries are not sufficiently explicit.

Victoria Park.—According to *Notes and Queries*, the last occasion on which an Act of Parliament was vetoed by the Crown was on March 11th, 1707, by Queen Anne.

Lapidary.—The attempt to fix a price for the opal is idle; each opal has its distinctive beauty and charm, and the comparison of weight, all-important in what may be called, by comparison, monotonous gems, is here worthless. Stones for rings or brooches vary from five shillings to £100; and, for specimens of extraordinary distinction, as much as £1,000 has been paid. It is said that £50,000 has been refused for an opal now in the Museum at Vienna. The fire opal has been imitated, but art has failed to produce a copy of the rainbow tints—always varying and always charming—of the precious opal.

Metric.—The absurdities in British weights and measures are numerous and glaring. In Monmouthshire the weight is 80lb. of wheat to the bushel; at Chester, Shrewsbury, and Market Drayton, 75lb.; at Stafford and Wolverhampton, 72lb.; Bristol, Wakefield, and Leeds, 60lb.; in Bideford and Torrington, 70lb.; at Warsall, 66lb.; at Aberystwith, 65lb.; at Carmarthen, 64lb.; at Boston, 63lb.; at Aylesbury, Cirencester, Dorking, Farnham, Petworth, Uxbridge, Midhurst, Oxford, Chichester, Brighton, East Grinstead, and other places, wheat is sold by the load of 5 qrs.; at Hitchin, by the load of 4 or 5 bushels; at Pontefract, by the load of 3 bushels; at Bedford, by the load of 5 bushels; at Stowmarket, &c., the load consists of 488lb.; at Ulverston, the same denomination means 14¼ quarts; at Bridgenorth, wheat is sold by the bag of 11 score; at Much Wenlock, by the bag of 11 score 1lb.; at Ludlow, by the bag of 11 score 10lb.; while in other market towns the bag means as much as 12 score, or as low as 9 score 10lb. At Whitehaven wheat is reckoned per 14 stones; at Nottingham and Grantham, per 36 stones; at Malton and Scarborough, per 40 stones; at Newcastle, Darlington, &c., the boll means 2 bushels; at Carlisle, 3 bushels; and in Scotland, 4 or 6 bushels, according to the kind of grain. At Beccles, and other places, a coom represents 4 bushels. At Preston, &c., we find wheat sold by the windle, or 220lb.; while in Denbighshire, wheat is reckoned by the hobbit of 168lb., barley by the hobbit of 147lb., and oats by the hobbit of 105lb. Barley and oats are also sold at other places by variable measures, which are understood only on the spot. Nor is the absence of uniformity confined to grain alone. Butcher's meat, for instance, is reckoned by the stone of 8lb. and of 14lb.; and occasionally we still observe the "Dutch" stone quoted in reports of some cattle fairs in Scotland. A tod of wool may mean either 28lb., 28½lb., 29lb., or 32lb.; while a stone of the same article has even a greater range in its meaning, according to locality, for it may be read as 12½lb., 14lb., 15lb., 16lb., 16½lb., 17lb., 18lb., 19lb., 24lb., and even 28lb., of 22oz. to the pound. Surely there is enough variety in this case to suit every taste.

J. M. S.—In the trades mentioned by you, the rate of wages varies according to the skill of the worker, but in very few cases is it higher than in this country.

Vulcan.—In reply to your remarks on reading, we would refer to the words of the author of the *Doctor*:—"I have heard of a man who made it a law for himself never to read a book again which had greatly pleased him on a first perusal, lest a second reading should disturb the pleasurable impression which he wished to retain of it. This person must have read only for his amusement, otherwise he would have known that a book is worth little if it deserves to be perused but once; and, moreover, that as the same landscape appears differently at different seasons of the year, at morning and at evening, in bright weather and in cloudy, by moonlight and at noonday, so does the same book produce a very different effect upon the same reader at different times and under different circumstances."

"WORKING MAN" LIFE-BOAT.

We have much pleasure in publishing the first list of subscriptions, not exceeding £1 in amount, to the Working Man Life-Boat Fund, received by us up to the date of our going to press. In compliance with a desire expressed by many of our friends, we postpone until a future day, the date of which will be announced in our next number, the acknowledgment of subscriptions exceeding £1 in amount, so as to afford each competitor an equal chance for the silver medal kindly offered by the committee of the Metropolitan and Provincial Working Classes Industrial Exhibition. Printed subscription lists will be forwarded on application by letter.

NOTICE.—The readers of the "Working Man" are solicited to bring the following announcement under the notice of any of their friends whom they may think will be interested.

Metropolitan and Provincial

WORKING CLASSES' EXHIBITION and INDUSTRIAL FESTIVAL, to be held at the AGRICULTURAL HALL, London, and opened on SEPTEMBER 3rd, 1866.

TO EXHIBITORS.

Contributions of Skilled Workmanship, or Amateur Productions, will be accepted from all parts of London, the Provinces, Scotland, Ireland, and the Colonies. For the benefit of Provincial Exhibitors, the Railway Companies have liberally offered to return unsold goods free, so that the expense of carriage will be but half the usual charge. Application for space to be made at once.

SPECIAL PRIZES.

The Council of the above Exhibition have much pleasure in announcing that, in addition to the MEDAL OF MERIT, designed for the occasion by J. S. and A. B. WYON, Esqs., the following SPECIAL PRIZES have been liberally offered by the gentlemen named, for the production of Articles to be Exhibited at the Agricultural Hall in September next, namely—

£15 0 0 in Money, or Silver Cup, for the MOST USEFUL INVENTION. Open to all Classes. The Gift of the Directors of the Agricultural Hall Company.

£10 0 0 in Money, or Silver Cup, for the best PAINTING IN OIL. The Gift of the Directors of the Agricultural Hall Company.

£5 0 0 in Money, or Silver Cup, for the second best OIL PAINTING. The Gift of C. COMFORT, Esq.

£5 0 0 in Money, for the best WATER-COLOUR DRAWING. The Gift of J. HARRIS, Esq.

£3 3 0 for the best GOLD BROOCH and EAR-RINGS, of Original Design, which can be sold for £10. (Sale for that sum to be permitted if required.)

£2 2 0 for the best pattern, Birmingham make, GILT BRACELET, BROOCH, and EAR-RINGS, which can be sold for £3 3s. (Sale for that sum to be permitted if required.)

£2 2 0 for the best Specimen of WHITBY JET JEWELLERY.

£2 2 0 in Money, for the best WORKING MODEL of a STEAM-ENGINE. The Gift of W. J. W.

£2 10 0 for the best ARTICLE OF UTILITY, made by an Amateur. The Gift of R. MURRAY, Esq.

£2 2 0 and a Silver Medal, the Gift of R. MURRAY, Esq., for the best WORKING MODEL of a MILL to grind Stale Crusts into Flour.

£2 2 0 for the best PEN-AND-INK DRAWING. The Gift of — STRAKER, Esq.

£2 2 0 for the best Original Contrivance that may be suggested for improving the Fittings of WORKMEN'S DWELLINGS.

£2 2 0 for the best Specimen of SHEFFIELD CUTLERY. The Gift of T. RUDKIN, Esq.

£2 2 0 for the best Pair of LADY'S BOOTS. The entire work to be done by Exhibitor.

£2 2 0 for the best Specimen of INLAYING IN WOOD. The Gift of C. A.

£2 2 0 for the best Specimen of WOOD CARVING. The Gift of J. S. and A. B. WYON.

£2 2 0 for the best Specimen of CABINET WORK, made by an Apprentice who has served not more than four years to his trade. The Gift of Mr. I. HAYNES.

£2 2 0 and a Silver Medal for the best Specimen of ORNAMENTAL TYPOGRAPHY, consisting of a Quotation from Shakespeare, displayed and Printed in Colours, to occupy a royal 8vo page.

In addition to the above, the

EXHIBITION SILVER MEDAL

will be awarded to the Exhibitors of the best Specimens of

Household Furniture.	Stained Glass.
Hammered Iron-work.	Artificial Flowers, from Nature.
Watch-Case Engraving.	Working Model of a Steam Vessel.
Engraving on Glass.	Statuette, in Plaster, or other Material.
Coventry Ribbons.	
Design for Paper Hangings.	
Embossing in Metal or Electro-Plate.	

☞ *Medals will also be awarded for other Articles which may be deemed worthy of especial distinction.*

All objects must be the work of the Exhibitor. In cases where Articles are the property of Employers, the name of the firm permitting their exhibition will be given in the Catalogue.

FORMS OF APPLICATION FOR SPACE may be obtained by sending a stamped and directed envelope to the Secretary, Mr. W. J. WATTS, 7, Birchmore Terrace, Cardington Street, Hampstead Road, London, N.W., or by application to any of the Honorary Agents. To be returned, filled up, on or before June 30.

Sec.* [32

The Original Chlorodyne, Invented by R. FREEMAN, Pharmaceutist, is allowed to be one of the greatest discoveries of the present century. It immediately relieves and cures Coughs, Colds, Consumption, Influenza, Bronchitis, Asthma, Whooping Cough, Cramp, Spasms, Gout, Diarrhœa, Dysentery, &c.

EARL RUSSELL communicated to the Royal College of Physicians and to Mr. Freeman that he had received information from Manilla that the only remedy of any use in Cholera was Chlorodyne.—*Lancet*, Dec. 31st, 1864. See *Times*, Nov. 14th, 1865. [27

Freeman's Original Chloro- DYNE.—The *Medical Times*, Jan. 13th, 1866, states—"It has an immense sale amongst the public, and is prescribed by scores of orthodox medical practitioners, and, of course, it would not be thus singularly popular did it not supply a want and fill a place."

Freeman's Original Chloro- DYNE engraved on the Government stamp outside every bottle. Sold by the Inventor and Manufacturer, R. FREEMAN, 70, Kennington Park Road, London, S., and most Chemists. In bottles, ¼ oz., 1s. 1½d.; 1½ oz., 2s. 9d.; 10 oz., 11s.; 20 oz., 20s.

Caution! Beware of spurious, deceptive, and dangerous imitations. Ask for Freeman's Original Chlorodyne, and see that you have none other. [25

PRICE TWOPENCE.

Upright Shoemaking. An ADDRESS TO WORKING SHOEMAKERS AND OTHERS ON THE EVILS OF THE "SEAT," AND THE ADVANTAGES OF THE "UPRIGHT BENCH;" with a few Practical Hints to Persons interested in the Promotion of Industrial Schools and Reformatories. The Planet Permanent Building

AND INVESTMENT SOCIETY, Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and all further information may be had of EDMUND W. RICHARDSON, Secretary.

CHILDREN'S DIET. [16

Prew and the Fine Weather.

The weather continues remarkably fair;
The poor and the wealthy its influence share;
Delightful excursions by sea and by land,
And summer enjoyments, are everywhere planned.
PREW'S elegant clothing we never should miss
At a beautiful season of sunshine like this.
Whatever new garment you purpose to buy,
B. PREW at his "Wardrobe" can daily supply.
The Capes and the Overcoats, faultlessly made,
In novel and various styles are displayed;
In light woven fabrics the garments appear,
All neatly designed for the time of the year:
The Dress Coats and Frock Coats, as all will admit,
Are perfect in quality, fashion, and fit;
And the Waistcoats and Trousers, in novel display,
Are termed the most beautiful styles of the day.
With equal approval each purchaser views
The JUVENILE CLOTHING at BENJAMIN PREW'S.
The styles are exceedingly novel and neat,
And parents acknowledge the fashions complete;
And be it remembered that savings are made
By parties who patronise PREW in his trade.

Liveries, &c. Always a choice from 2,000 Children's Knickerbocker suits, from 12s. 6d.

B. PREW, Practical Tailor and Juvenile Outfitter. The Great Metropolitan Wardrobe, 294 and 295, High Holborn, fifteen doors west of Chancery Lane. [32

Gathered from the Waters.

For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1857, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the Shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,600 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C. [10

John Moseley and Son,

17 and 18, King Street, and 27, Bedford Street, Covent Garden, London, W.C., CUTLERS, GENERAL MERCHANTS, and MANUFACTURERS OF MECHANICAL TOOLS—Saws, Tool Chests, Turning Lathes, Garden Tools, &c., Wholesale, Retail, and for Exportation. Established a Hundred Years. Reduction in the Price of Moseley's Warranted Saws, Genuine Gauged Plates:—

	£	s.	d.
28-inch Best Half Ripping Saw ...	0	8	0 each.
26 ,, Hand Saw	0	7	6 ,,
14 ,, Brass-back Sash Saw	0	8	6 ,,
14 ,, Iron-back ditto...	0	5	6 ,,

Saws same make, Second Quality (by some called best) of each of the above, 1s. less.

Carriage Free (if to the amount of 40s.) on receipt of Post Office Order, or postage stamps.

N.B.—These Saws are the same make as those that have given such great satisfaction for the last forty years.

NOTICE.—Messrs. MOSELEY and SON beg to announce that, in order to enable Country Workmen and others to obtain their superior Tools and Cutlery, they are now prepared to forward, direct from their Establishments, Parcels to the amount of £5 and upwards, to any part of the Kingdom, Carriage Free. Cash by Cheque or Post Office Order.

Moseley's Patent Electric Bells, Railway Signals, &c. Superior Galvanic Machines, from 18s., &c. &c. These machines are strongly recommended by the faculty for the cure of Rheumatism, &c. &c. [11

Baker and Baker's True

UNCOLOURED TEAS are imported and sold Free from all Adulteration; they can, therefore, be relied on for Uniform Good Quality, Fine Flavour, and Lasting Strength. Sold by Chemists, Confectioners, &c., in most Towns. [12

EASY MODE OF PAYMENT.

Every Description of General

DRAPERY, TAILORING, AND OUTFITTING, At Moderate Prices.

TERMS: One Shilling in the Pound per Week.

H. J. SEARLE, 125, Old Kent Road. [17

THE "CITY" HAT COMPANY'S

Only retail address is 109 and

110, Shoe Lane, eight doors from Fleet Street.

The celebrated Paris Napped Hats..... 3s. 6d. each.
Superfine quality ..... 6s. 6d. ,,
Best Hats (these are unequalled) ..... 9s. 0d. ,, [18

In the Press.

English Cottages for the

MECHANIC, OR WORKING MAN, AND AGRICULTURAL LABOURER; giving *Perspective Views, Plans, Elevations, and Detail Drawings*, Stairs, Doors, Windows, &c. *Bills of Quantities* to each house, and a general Specification of the whole. These Cottages have been so arranged as to make HEALTHY MORAL HOMES FOR THE WORKING MEN of England. Containing 24 plates, imp. 4to, executed in the best style, with letterpress description. In six parts at 2s. 6d. each. To subscribers to the whole series, the letterpress will be given with the sixth part. Publishers, ACHLEY & Co., 106, Great Russell Street, Bedford Square, London, W.C.

A New List of Books and Prospectus of Works in the Press sent free to order by post. [13

Inventors Assisted in Secur

ing, Carrying Out, and Disposing of their Invention. Apply to B. BEOWNE and Co., British and Foreign Patent Office, 49, King William Street, London Bridge. A Pamphlet, gratis, on Cost of Patents, may be had on application. [14

Inventions Protected by Patent

OR REGISTRATION at fixed and moderate charges. The "Inventor's Manual," free by post, or gratis on application. Apply to Mr. BREWER (late Barlow and Co.), 89, Chancery Lane, London.—Established Twenty-one Years. [15

The Operatives' House

BUILDING COMPANY (LIMITED). Established to provide Improved Dwellings for the Working Classes.

Working Men's Societies are invited to communicate with the Secretary, at the Company's Office, 10, John Street, Adelphi, W.C., where Prospectuses may be had.

W. H. ROBINSON, Secretary. [9

Magic Photographs.—Sur

prising and interesting amusement. Every one is able to produce with a few drops of water an instantaneous photograph. 1s. the packet, with printed instructions, or post free for 13 stamps, from the Manufacturers and Patentees, Messrs. ANGERERS, SON, FRUWIRTH, and Co., 146, Cheapside, E.C.

Magic Portraits.

"Any child can astonish the family."—See *Standard*.

Magic Portraiture.—To be

enabled to produce your OWN PORTRAIT by Magic Photography, with a few drops of water only, causing endless fun and amusement, send your carte de visite and 30 stamps to Messrs. ANGERERS, SON, FRUWIRTH, and Co., 146, Cheapside, E.C. One dozen with materials and printed directions for instantaneous production will be returned with the original within ten days. [19

Hall's "Lung Restorer"

gives instant relief in Coughs, Asthma, Hoarseness, Sore Throat, &c. Mr. R. Brooke, Mirfield, near Leeds, writes, after suffering over ten years with an asthmatic cough, "Three 1s. 1½d. bottles cured me." Prepared by THOMAS HALL, Chemist, 6, Commercial Street (City side Great Eastern Terminus), London, and sold by all Chemists, in bottles, at 1s. 1½d., 2s. 9d., &c. [20

The Best Remedy for Indi

GESTION, Bilious and Liver Complaints, FRAMPTON'S PILL OF HEALTH.—Sold by all Medicine Vendors, at 1s. 1½d. and 2s. 9d. per box, or obtained through any Chemist. [21

The True Nobility of Capital.

To honourably acquire wealth is a great thing; to make a good and noble use of the wealth so obtained is greater still. Too frequently the fortunes acquired in business are thoughtlessly expended in objects which leave out of sight the interests and welfare of those who have assisted in the production of the wealth so acquired. Availing himself of the narrowest interpretation of the few simple laws which regulate the relations between capital and labour, the selfish and covetous wealth-seeker bestows not a thought upon those whose labour has helped to swell his riches. He pays them their stipulated wages, and there the matter terminates: he has nothing more to do with them—the contract is at an end. This, however, is an extremely false and short-sighted view of the question. If capital has its rights, it has, also, its duties, and where those duties are properly fulfilled we hear little of the fierce antagonism which is so frequently found existing between capital and labour. The bitter heart-burnings and violent spirit of animosity, which have at times raged with such intensity throughout the industrial world, have usually taken their rise, not in the inevitable clashing of really diverse interests, but rather from the existence of mutual misunderstandings and the want of genial sympathy—a want occasioned by long-continued estrangements—between employers and employed. The intelligent mechanic, no less than the educated capitalist, knows—and not only knows, but feels—that the interests of capital and labour are identical, and he cannot resist deploring the existence of that broad and yawning social chasm which relentlessly divides the two great sections of industrial society. All the efforts of the modern social philosopher are directed to the purpose of bridging over this fatal gulf, and of uniting the two contending forces; but such a result can only be obtained by the combined action both of masters and men. All honour, then, to those individuals—whether workmen or employers—who have made a step in this direction, especially those capitalists who, like our Crossleys, Salts, Bazleys, Akroyds, and others, have not thought it beneath their dignity to direct their attention to the best means of promoting the comfort and welfare of those who have toiled so long and so successfully for them. It is the proud glory of this country that the number of such men is so large, although it is certainly small compared with what it might be. It is these men who form the true nobility of capital, who have shown the world that there are other objects, far purer and nobler, than mere money-making, on which the sons of fortune may set their hearts. The late William Brown, when he expended so large a portion of his wealth in founding the Liverpool Free Library and Museum, showed a true and earnest appreciation of the duties of capital. He recognised the Divine law which bade the strong to help the weak, and acted accordingly. A gift more useful or more practical than that made by him could not have been devised; but there are other ways in which capital can be made to assist labour, as in the case of Saltaire, that magnificent palace of industry, where the social and physical condition of the employed forms the true eulogium of the employer. Again, there is the example of Samuel Morley, whose portrait adorns our columns this week. Mr. Morley may fairly be said to represent the new class of merchant capitalists, the number of whom are constantly increasing. There are few practical movements, having for their aim the promotion of the happiness and welfare of the working classes, which he has not assisted in some shape or another. The Temperance cause is considerably beholden to him for much of his sympathy and help; and in the south of London his name has become treasured by the artisan population as that of one who is always ready to assist in any practical manner the efforts of his poorer brethren to ameliorate their condition. The details of his life are few, and comparatively uninteresting, apart from his connection with the cause of social progress. He was the youngest son of the late John Morley, Esq., and was born in 1809. In 1841 he married Rebekah Maria, daughter of Samuel Hope, Esq., of Liverpool. In 1865 he contested the borough of Nottingham, when he was returned at the head of the poll; but during the present year he was unseated, in consequence of bribery having been committed, although without his knowledge or sanction, by some indiscreet persons acting in his behalf. As the head of a large business establishment in the City of London, Mr. Morley has taken it upon himself to set an example to his brother employers, by exerting himself to promote in every possible manner the welfare of those employed by him. The Early Closing movement, and kindred efforts for improving the condition of our workers, have found in him a firm and unfaltering advocate. He has also subscribed largely for religious purposes, principally in connection with the Congregationalists, of which body he is a member. As a magistrate for the county of Middlesex, Mr. Morley has proved assiduous and impartial in the discharge of his duties, gaining the confidence and esteem of his brother magistrates. The success of the two South London Working Classes' Exhibitions was attributable in no small degree to the liberal and ready manner in which Mr. Morley came forward for the purpose of guaranteeing the promoters—principally working men—against loss, a fact still gratefully borne in mind by the artisans of South London, with whom the honoured name of Samuel Morley is deservedly popular. Well may the country feel proud of such men as Samuel Morley. It is to such thoughtful, large-hearted, and noble-minded individuals that the cause of social progress owes so much. Had we more of such men the raging fires of class jealousy which yet linger in the hearts of many of those born to a life of hardship and toil would disappear, and a more kindly and unrestrained degree of intercourse be found subsisting between the capitalist and labouring classes of the community. But this will yet be. The true nobility of labour and the true nobility of capital will, at no distant period, insensibly unite with each other, and become the all-powerful lever which is destined to achieve in this country the solution of the long-vexed question as to the best means of bringing the various classes of the community into harmonious relationship with each other. This is the great and glorious work of the future; the task not only of ourselves, but of our children. As one of our poets has earnestly sung—

SAMUEL MORLEY, ESQ.
(*From a Photograph by John Burton and Sons, Leicester.*)

"Far more it imports men to know,
To feel, to prove each other's worth,
Than on that fame their thoughts bestow,
To which the past has given birth—
Call forth the *living* spirit's powers,
And use them for this world of ours!

"And let the good be named 'The Good;'
The true, 'The True;' the brave, 'The Brave'—
Titles not bought and sold for blood
Like those our war-girt monarchs gave—
And let the just be still 'The Just,'
So men shall know wherein they trust."

ONLY one-eighth of the great State of Illinois is yet under cultivation.

The Postmaster-General.

There is no general whose command is looked upon with so much satisfaction by the public as that of the Postmaster-General. His plans are those of progress, not destruction; and he is the only commander whose army is productive. Instead of being the instrument of new burdens upon the people—as naval and military commanders invariably prove to be, in spite of themselves, and by the costly and destructive nature of their operations—the Postmaster-General, filling a happier office, and exercising a beneficent command, finds the means of augmenting the national revenue. Yet he, too, makes war, but it is upon ignorance. No agency ever devised has assisted more in the diffusion of knowledge than the Post-office. The schoolmaster teaches the art of correspondence, the Postmaster-General devises means for circulating it. The printing-press was never half so fruitful in effects of good until wise measures were adopted at the Post-office for carrying its weekly, and indeed hourly, productions over the world. The late Mr. W. H. Ashurst, the father of the present solicitor of the Post-office, united with Sir Rowland Hill to promote the system of penny postage, and afterwards the book-post system, with the object of diffusing knowledge in the interest of the working class. Railways were in their infancy when these ideas were first urged. It was very early to foresee, and it implied very great shrewdness to prove, that the plan of cheap diffusion would answer as a pecuniary speculation. There is little doubt that what has been termed an ocean penny postage would prove in time equally productive. It probably awaits some improvements in ship-building and steam navigation to render it possible, which will come in due course. Its effect upon human life and international intercourse is incalculable. A penny postage to all nations would render the world one family, in a way exceeding dreams of poesy. Working men could then communicate with their brethren all the world over. Facts about trade, wages, schemes of improvement, of which no use is ever made, of which working men live and die and never once hear, would then be circulated every few weeks throughout the world. International and industrial exhibitions, now got up only at intervals of years with great cost and difficulty, would become frequent, economical, and easy.

The Post-office system, which has grown marvellously, is extending itself—or, rather, the sagacity of the Postmaster-General and his advisers and assistants, is yearly extending it. The Postmaster-General has just presented to Parliament his twelfth report of the operations conducted by his command.

For some years an addition of about 400 per annum has been made to the number of letter receptacles, but in 1865 no less than 616 additional receptacles "were," says the report, "brought into use." Why not say established? "Brought into use" seems to imply that the receptacles were previously in existence, and only now made use of. The familiar term "letter-box" seems discarded, and "receptacles" takes its place. Perhaps, strictly speaking, there are no "letter-boxes" now, if ever there were. Letter-bags there may have been, and are still, but unless boxes have every variety of shape—including the hole in the wall, the sack tied to it, or basket put under it—"receptacle" is, no doubt, a more generic, apt, and comprehensive term.

In towns, as every one knows, post deliveries are free; but in country districts a charge is made for delivery beyond the postal range. During the year 1865, 437 new "free deliveries" have been established where none existed before; 182 *additional* free deliveries have been put into operation; and in 111 places free deliveries have been *extended*. Night and day mails *from* London have been extended to 410 new towns, and 266 new towns have now night and day mails *to* London. The increase of mails to London is considerable. Two new towns have seven daily mails to London. Mails have been accelerated, so that vast and distant districts obtain their letters two hours earlier than in 1864, and are enabled to dispatch replies half an hour later. In remote parts of Scotland, where there was postal communication only three days a week, there are now deliveries six days a week.

In London, as our readers are aware, there exist postal districts, and letters are marked N., N.W., E., E.C., &c., meaning North, North-West, East, East-Central Districts, which enables a more rapid assortment and delivery of letters to be made. The Postmaster is extending this plan to large towns, Liverpool being one. A year ago it required thirty-eight hours for two letters and one reply to pass between Jones and Smith. Thus, if Jones offered to sell a table to Smith for £10, and Smith wrote back and said he would give £8, if his offer was accepted at once, it took thirty-eight hours to complete the transaction. By the new arrangement of district deliveries in Liverpool, the same transaction can be effected in thirty-three hours. In 1863, one letter and one reply to it might take twenty-four hours; now it can be effected, at the most, in seventeen. The average time was nineteen hours, it is now only eleven. The shortest time was eight and a half hours, it is now only five hours. Every one having to write on matters of business or family interest can estimate the value of the time thus saved.

The benefit is shown in a striking way. Under the operation of the new system the local letters have increased half a million per year in the Liverpool district alone.

The general increase of letters, books, newspapers, and parcels sent through the post is something marvellous. In 1863, letters increased 36,000,000; books and newspapers augmented 2,000,000. In 1864, letters increased 36,000,000 more; books and newspapers 6,500,000; and samples and patterns 625,000. In 1865, letters increased again 41,000,000; books and newspapers, nearly 2,000,000; and samples and patterns, 660,000. Last year the gross total of articles sent through the Post-office rose to—

Letters	720,460,000
Books and newspapers . . .	97,250,000
Samples and patterns . . .	1,280,000
In all	818,990,000

The kind of articles sent now through the Post-office annually is something incredible. They included, in 1865, 59,000 samples of tea, 47 carpets, 5 samples of oil, 563 shirts, 207 pieces of iron, 4 weighing machines, 20 samples of preserved meat, 5 felt hats, 1 cricket ball, 1 bell, 28 pieces of Atlantic cable, 250 Pharaoh's serpents, 1 opera glass, 13 samples of grease. All sorts of articles conceivable, excepting live animals—and they will doubtless go before long—have been sent through the Post-office.

The increase of money-order offices, the development of Post-office savings banks and insurance, form very remarkable topics in the Postmaster-General's twelfth report. The financial result is quite in keeping with the wonderful facts of the departments noticed. From 1855 to 1860 the Post-office yielded half a million of revenue. During the five years from 1860 to 1865 it averaged one million a year gained for the State. Indeed, during 1865 the money earned by Lord Stanley of Alderley, the Postmaster-General, was close upon one million and a half. What is of yet more importance is, that his lordship is of opinion that the revenue of the Post-office may be indefinitely increased, and that, if the prosperity of the country is maintained, the Post-office may, in a few years, yield a net revenue equal to the produce of the income-tax. This is certainly a consummation devoutly to be wished. Thus, we may have Chancellors of the Exchequer one day who will see their way to raising a revenue without taxation. At present, our army and navy and million of paupers lie a dead weight upon the country. Can the genius of no political economist contrive to make them productive? Surely, something is possible in the direction of self-support, if not of profitable production. It would be well to place them successively under the command of Lord Stanley of Alderley.

Something about Coal.—From information collected at the Museum of Practical Geology, it would seem that, last year, about 96,000,000 tons of coal were raised. It would probably be safe to add to the number at least 20,000,000 more tons for waste; or say, in round numbers, that we are now raising about 120,000,000 tons yearly. In 1860, the quantity raised was 80,000,000 tons; and in 1856, about 66,600,000 tons. These numbers are so large, that it is difficult to form an accurate conception of what they really mean. *With 100,000,000 tons, a girdle of coal three feet wide and about seven high might be put round the earth.—Quarterly Review.*

Grievances of Ploughmen and Rural Labourers.

BY JAMES BEGG, D.D.

IMPERFECT COTTAGE ARRANGEMENTS.

The recent unexpected combination of ploughmen in certain districts, to secure an advance of wages, has already been productive of fruit. In addition to a pretty full discussion of their circumstances and claims in the country generally, at the last Haddington hiring market, the ploughman for whom cows are not kept (of which more afterwards) received a general advance of from £1 to £2 a year each. The agitation has, on the whole, been conducted and met in a very good spirit, and no doubt is yet destined to be productive of still greater good.

One great difficulty in understanding such an agitation, consists in the variety of ways in which ploughmen and farm labourers are paid, and especially the extent to which they are paid—not in money, but in kind. From Lord Shaftesbury's letter to the *Times* on the subject of the Dorsetshire labourers, as well as from all the information that can be gathered on the subject, it is evident that this state of things is all but universal. At a meeting of Midlothian ploughmen, held at Davidson's Mains, near Edinburgh, and reported in the *Daily Review* of December 29th, 1865, Mr. Thomson, of Corstorphine, the chairman, gave the following account of the ploughman's wages in that district, with his own idea of the causes which prevented their increase. The statement is worth reading, and gives rather a different theory of the operation of gratuities from that which we have lately seen. He said:—

We have on an average £22 a year in wages. Some have more than this, and some have less. We have also six and a half bows of meal, four bows of potatoes, coals driven, and a free house. Now, with £22, taking the meal at £2 per load, that is £28 10s.; the potatoes, at 10s. per boll, is £2 more, making £30 10s. Then we have £3 for house-rent, which comes to £33 10s., and 10s. for coals makes the whole, perhaps, £34. So that we have scarcely 13s. 1d. per week. Now, gentlemen, I have not understated our case, and I think, if you take a right average, it will stand 1s. less, or 12s. per week. Now, take a look and see how other classes of workmen in this part of the country are paid. Take railway companies, shipping companies, and mill men, and you will find that on an average they have from 15s. to 20s. per week, and they work ten hours a day for six days in the week; while we have only 12s. a week, and work at least twelve hours every day, and at least three hours every Sunday; so that we are at least 2s. below a common labourer. But let us see if we cannot find the cause of this oppression. We do not consult one another. We work too much in the dark. We do not know each other's minds, whereas by meetings of this kind we know what we are to ask. By helping one another we bring combination against combination, and thereby gain a position we would never attain by remaining single. There is still another cause which I would like to say a few words about; that is, there are some employers who are in the habit of giving presents to their men. It is the custom amongst some masters to kill a pig or two, according to the number of their men, and to divide it among them; likewise pickles of wheat now and then, to make scones of. Now you will say that that cannot hurt us; but it does hurt us—ay, and more than we are aware of. Those who get it will not ask up their wages, and for this reason, that they are, perhaps, far better than if they were to get all we ask for; so that we lose their support, and the masters boast of their cheap men, while in reality they are paying far more than their neighbours. They keep down wages, and give in a present what might be given as wages.

There is, no doubt, a great deal of truth in what the *Times* urges in regard to the amount of practical comfort often secured by this mode of payment in kind; but, on the other hand, the operation of the system ought, undoubtedly, to be limited, and, if possible, reduced to something like uniformity, so that to calculate wages would not only be possible, but easy. There are certain things—as, for example, a good cottage and garden, with the cartage of coals and a supply of milk—which might always be reckoned as part of the wages of ploughmen and agricultural labourers, and might be universal; but if we proceed much farther, disputes in regard to the quality and value of the agricultural produce are apt to arise between giver and receiver; bad blood is engendered, and the whole question is apt to be involved in uncertainty and confusion. A certain definite payment in money, at short

terms, with a few other stipulations absolutely necessary, would reduce the problem to perfect simplicity and uniformity, and if the present agitation leads to this result, it will secure a great advantage to all parties.

By all means let the ploughmen and agricultural labourers sell their labour, which is their only capital, at its full and fair value. Upon this general aspect of the question, we hold that the ground is clear, and we do not at present dwell upon it. But there is one feature of the case which we deem of special importance, viz., the ploughman's home; and we are confident that one of the first and most essential improvements in the state of our agricultural population is to secure a uniform set of roomy and comfortable cottages, with gardens, in connection with every farming establishment. The state of the houses of agricultural labourers is often at present disgraceful. We propose to point out some of the forms of hardship and evil connected with this department of the subject—connected with imperfect cottage arrangements — the bothy and farm kitchen systems, the bondage system, and otherwise. At present, we shall confine our attention to the first of these.

It has often been remarked as singular, that the progress of agriculture has not only not always carried along with it as a fixed result the elevation of rustic comfort, but that, in proportion as farming has improved, as rents have increased, and cattle become more comfortable, the farm labourer has sometimes sunk into deeper social degradation. The poet Burns, who had himself been a ploughman on the small farms of the west of Scotland, where the farmer often holds his own plough, was astonished to find, when he came to the palatial farming establishments of the Lothians, that the ploughman, although, perhaps, more perfect in his work, and certainly in a much richer district, had sunk into a much lower social position. The county of Norfolk represents, probably, as good farming as any in England, and was amongst the earliest districts in the south to start in the race of improvement; but it is from this county that, probably, amongst the loudest complaints have come in regard to the social degradation of the peasantry.

The defects which exist in connection with rural cottages may be summed up under several heads:—

The cottages themselves are sometimes very imperfect. Many of them have only one apartment. By an easy adaptation of our census schedules, the extent of this evil could easily be ascertained every ten years, and I am certain it is very general. Till I took possession of my former charge as Minister of Liberton, in 1835, I had scarcely ever seen a house with only one apartment. In the west of Scotland, where my youth was spent, the poorest cottages had almost invariably at least two apartments, called, locally, "a but and a ben." I was not a little shocked to find the case so totally different in my new locality—to find persons often ill of infectious diseases, and yet no means of separation; to find a dead body sometimes in the apartment in which the humble inhabitants were partaking of their frugal meal. It was easy to conjecture, besides, that many other evil moral results must spring from such a state of things, so fitted to degrade the mind and to blunt all moral feeling. And yet this state of things was at that time all but universal in one of the best cultivated and highest rented districts in the United Kingdom. I am happy to say that partly, no doubt, as the result of considerable exposition and effort, a wide change has since taken place, and there are now few ploughmen's houses in that parish which have not two or three apartments. But the very same state of matters still continues in many other districts. Some cottages, besides, are damp and unhealthy. I remember when visiting, a few years ago, the new cottages of Lord Aberdeen in the north, to have seen a foundation which had been dug out for a cottage, but which his lordship had humanely rejected. It was a low, damp place, and probably regarded as of no practical use; but the rejected foundation was standing full of water, indicating plainly what the house would have been. You often see, in the older cottages, the black or green damp climbing half-way up the wall, the floor being often also considerably below the level of the surrounding earth. The result of this is that rheumatism and other diseases, notwithstanding his healthy out-door employment, often make the poor ploughman a bent and broken-down old man in middle life. Any place, in short, however unsuitable, is sometimes reckoned good enough as the site of a ploughman's cottage, and the sanitary science of modern times is sometimes little known or regarded. Many of the older cottages are, for the sake of economy, made without ceilings, and the ploughman is obliged to protect himself from the cold by means of canvas and other appliances. Some of the older ploughmen have told me, indeed, that at one time many of their houses had neither doors nor windows. The cottage consisted, sometimes, simply of four bare walls, with a roof, and the ploughman was required to bring his doors and windows along with his other furniture. Some cottages, again, have no gardens, or very small ones. A rood of land is a great advantage in the country to a ploughman or labourer with a family, both as affording an opportunity of spending his leisure hours innocently and to advantage, and of securing a supply of wholesome vegetables, which cannot otherwise be bought. Some cottages have no supply of good water, or a very imperfect supply. It is of great importance, as we have already said, to have cottages placed in a dry situation, and with a southern exposure; but it is also most important, for health and cleanliness, to have a copious supply of good pure water.

These are only some of the more prominent evils connected often with the cottages themselves. No doubt much has been accomplished of late years in the way of arousing public attention to the importance and urgency of the question, and some proprietors have shown a noble example in the erection of admirable cottages. These men deserve the utmost credit for what they have done, and to this part of the subject we shall advert again. But a vast work in this direction remains yet to be accomplished. The means of effecting this have yet to be decided upon; meanwhile, men's thoughts have been turned to the consideration of the question, and it cannot be long before a solution of the vexed problem will be found.

Self Help.

"As steady application to work is the healthiest training for every individual, so is it the best discipline of a state. Honourable industry travels the same road with duty; and Providence has closely linked both with happiness. 'The gods,' says the poet, 'have placed labour and toil on the way leading to the Elysian fields.' Certain it is, that no bread eaten by man is so sweet as that earned by his own labour, whether bodily or mental. By labour the earth has been subdued, and man redeemed from barbarism; nor has a single step in civilisation been made without it. Labour is not only a necessity and a duty, but a blessing: only the idler feels it to be a curse. The duty of work is written on the thews and muscles of the limbs, the mechanism of the hand, the nerves and lobes of the brain—the sum of whose healthy action is satisfaction and enjoyment. In the school of labour also is taught the best practical wisdom; nor is a life of manual employment incompatible with high mental culture." Thus writes Mr. Smiles, in his new edition of "Self Help," a work which ought to be found in every working-class library, forming, as it does, a stirring record of the feats which have been accomplished by the exercise of indomitable perseverance and unfaltering earnestness. The lesson to be learned from the book is, that there is no position so obscure, or station so lowly, but that a man can rise from them, if he so will it, to better things. Mr. Smiles gives several instances of this:—"Among those who have given the greatest impulse to the sublime science of astronomy, we find Copernicus, the son of a Polish baker; Kepler, the son of a German public-house keeper, and himself *garçon de cabaret;* d'Alembert, a foundling picked up one winter's night on the steps of the church of St. Jean le Rond, at Paris, and brought up by the wife of a glazier; and Newton and Laplace, the one the son of a small freeholder near Grantham, the other the son of a poor peasant of Beaumont-en-Auge, near Honfleur. Notwithstanding their comparatively humble circumstances in early life, these distinguished men achieved a solid and enduring reputation by the exercise of their genius, which all the wealth in the world could not have purchased. The very possession of wealth might, indeed, have proved an obstacle greater even than the slender means to which they were born. The father of Lagrange, the astronomer and mathematician, held the office of Treasurer of War at Turin; but having ruined himself by speculations, his family were reduced to poverty. To this circumstance Lagrange was, in after life, accustomed partly to attribute his own fame and happiness. 'Had I been rich,' said he, 'I should probably not have become a mathematician.'" Again, take the case of the late Mr. Heathcote, formerly M.P. for Tiverton, the inventor of the bobbin-net machine:—"When a little over twenty-one years of age, Heathcote married, and went to Nottingham in search of work. He there found employment as a smith and 'setter-up' of hosiery and warp-frames. He also continued to pursue the subject on which his mind had before been occupied, and laboured to compass the contrivance of a twist traverse-net machine. He first studied the art of making the Buckingham or pillow-lace by hand, with the object of effecting the same motions by mechanical means. It was a long and laborious task, requiring the exercise of great perseverance and no little ingenuity. During this time his wife was kept in almost as great anxiety as himself. She well knew of his struggles and difficulties; and she began to feel the pressure of poverty on her household; for while he was labouring at his invention he was under the necessity, occasionally, of laying aside the work that brought in the weekly wage. In years long after, when all difficulties had been successfully overcome, the conversation which took place between husband and wife, one eventful Saturday evening, was vividly remembered:—'Well, John,' said the anxious wife, looking in her husband's face, 'will it work?' 'No, Anne,' was the sad answer; 'I have had to take it all in pieces again.' Though he could still speak hopefully and cheerfully, his poor wife could restrain her feelings no longer, but sat down and cried bitterly. She had, however, only a few more weeks to wait; for success, long laboured for and richly deserved, came at last; and a proud and happy man was John Heathcote when he brought home the first narrow strip of bobbin-net made by his machine, and placed it in the hands of his wife."

The true self-helper is not deterred by failure. As Mr. Smiles justly observes:—"We learn wisdom from failure much more than from success. We often discover what *will* do, by finding out what will not do; and probably he who never made a mistake, never made a discovery. It was the failure in the attempt to make a sucking-pump act, when the working bucket was more than thirty-three feet above the surface of the water to be raised, that led observant men to study the law of atmospheric pressure, and opened a new field of research to the genius of Galileo, Torrecelli, and Boyle. John Hunter used to remark that the art of surgery would not advance until professional men had the courage to publish their failures as well as their successes. Watt, the engineer, said of all things most wanted in mechanical engineering was a history of failures. "We want," he said, "a book of blots." When Sir Humphry Davy was once shown a dexterously manipulated experiment, he said, "I thank God I was not made a dexterous manipulator; for the most important of my discoveries have been suggested to me by failures." Another distinguished investigator in physical science has left it on record that, whenever in the course of his researches he encountered an apparently insurmountable obstacle, he generally found himself on the brink of some discovery." Concerning a well-known common error, Mr. Smiles tells us that:—"It has been a favourite fallacy with dunces in all times, that men of genius are unfitted for business, as well as that business occupations unfit men for the pursuits of genius. The unhappy youth who committed suicide a few years since because he had been 'born to be a man and condemned to be a grocer,' proved by the act that his soul was not equal even to the dignity of grocery. For it is not the calling that degrades the man, but the man that degrades the calling. All work that brings honest gain is honourable, whether it be of hand or mind. The fingers may be soiled, yet the heart remain pure; for it is not material so much as moral dirt that defiles: greed far more than grime, and vice than verdigris. The greatest have not disdained to labour honestly and usefully for a living, though at the same time aiming after higher things. Thales, the first of the seven sages, Solon, the second founder of Athens,

and Hyperates, the mathematician, were all traders. Plato, called the Divine, by reason of the excellence of his wisdom, defrayed his travelling expenses in Egypt by the profits derived from the oil which he sold during his journey. Spinoza maintained himself by polishing glasses while he pursued his philosophical investigations. Linnæus, the great botanist, prosecuted his studies while hammering leather and making shoes. Shakespeare was the successful manager of a theatre—perhaps priding himself more upon his practical qualities in that capacity than on his writing of plays and poetry. Pope was of opinion that Shakespeare's principal object in cultivating literature was to secure an honest independence. Indeed, he seems to have been altogether indifferent to literary reputation. It is not known that he superintended the publication of a single play, or even sanctioned the printing of one; and the chronology of his writings is still a mystery. It is certain, however, that he prospered in his business, and realised sufficient to enable him to retire upon a competency to his native town of Stratford-upon-Avon." These are lessons upon which working men should carefully ponder; for their real deliverance from the evils, both social and physical, which afflict them is to be found in the proper application of the principles of the world-old doctrine, that God helps those who help themselves.

Landlord and Tenant.

Almost every person must occupy one or other of these relations at some period of life, but comparatively few—among working men especially — are sufficiently acquainted with the legal rules by which those relations are governed. We propose to give, in one or two papers, the substance of the English law respecting landlord and tenant of house or apartments; and, while as brief as possible, we shall endeavour to make the outline of practical utility to our readers.

The first step in the relationship is, of course, the letting and taking of a house; and as to this, it is a rule of law that the house is let for a year, and the tenancy is an annual one, unless there is an agreement to the contrary. Working men, in most cases, do not occupy as yearly tenants, but by the week, month, or quarter, as may be arranged with the landlord; but as the rules applicable to all tenancies are, in the main, the same, we shall treat more particularly of the tenancy especially recognised by the law—that from year to year.

THE AGREEMENT.

It is always advisable, in the interest of both parties, that there should be an agreement in writing as to the terms of the tenancy. In the case of yearly occupation, this agreement should take something like the following form:—

Memorandum of an Undertaking entered into this day of , between A B, of , and C D, of as follows:—

The said A B doth hereby let unto the said C D a dwelling-house, situate in , in the parish of , for the term of one year certain, and so on from year to year, until half a year's notice to quit be given by or to either party, at the yearly rent of pounds, payable quarterly, the tenancy to commence on next.

And the said A B doth undertake to pay the land-tax, the property-tax, and the sewer-rate, and to keep the said house in all necessary repair, so long as the said C D shall continue therein; and the said C D doth undertake to take the said house of A B for the before-mentioned term and rent, and to pay all taxes, except those on land, or property, and the sewer-rate, and to observe the other conditions aforesaid.

Witness our hands this day of

But, in some cases, the landlord agrees to pay all the rates and taxes, and this should be expressed in the agreement as follows:—

And the said A B doth undertake to pay all rates and taxes, of whatever nature or kind, chargeable on the said house and premises, and to keep the said house in all necessary repair, &c.

It occasionally happens that the clause relating to the sewer-rate is omitted from the agreement, and the payment of that rate then falls on the tenant; but ground-rent, land-tax, and property-tax are by law chargeable upon the landlord, unless the tenant undertakes to pay "all taxes," when the landlord is burdened with the property-tax alone. In ordinary cases, the ground-rent, &c., if not paid by the landlord, may be claimed of the tenant, but he is then at liberty to deduct the amount out of the rent, on his next payment to the landlord.

With regard to the local rates, the tenant is only liable for that portion of them which becomes due under his actual occupation; and arrears left by a previous tenant cannot legally be recovered from the last comer. But, to save trouble, it is always best to have the landlord's indemnification against back rates and taxes, and this should be placed in writing as follows:—

I, A B, landlord of the house and premises situate , now about to be taken and occupied by C D, do hereby agree to indemnify the said C D from the payment of any rent, rates, or taxes in arrear, prior to the day on which his said tenancy commences.

PAYMENT OF RENT.

Rent usually becomes due only at the end of the complete term for which the house has been taken, say month, quarter, or year; but in yearly occupation it is customary to insert in the agreement the clause above given as to quarterly payments, and the rent is generally payable on the quarter days—Lady Day, March 25; Midsummer Day, June 24; Michaelmas Day, September 29; and Christmas Day, December 25. Rent is due at the middle of the day when the stipulated term is complete; but while the tenant remains in occupation the landlord is not allowed to take proceedings to recover until the day following.

Whatever may happen to the house—should it even be burnt down or blown down—the tenant is still liable to the landlord for the rent, unless he has protected himself against such a contingency by special agreement: and in the case supposed, there is nothing in law to compel the landlord to restore the house to a habitable condition; but the tenancy, as before, can only be terminated by proper notice to quit.

Rent should be claimed by the landlord in person; or if by an agent, by one either producing the landlord's written instructions to receive, or well known as acting on his behalf. Receipts for those taxes which properly belong to the landlord, but which may have been paid by the tenant on demand, are legal tender to the landlord in whole or part payment of his rent; but, as a rule, payment should be made in the current coin of the realm, or by Bank of England note; and the landlord is justified in refusing to accept payment by cheque.

NOTICE TO QUIT.

In the absence of special agreement, a yearly tenancy can be terminated only on the delivery of six months' notice, that notice to expire at the precise period at which the tenant entered on his occupation. Thus, if he enter on Midsummer-day, he must give his notice on or before Christmas Day, in order to be entitled to leave on the Midsummer Day following. The notice should be in writing, and take something like the following form:—

I hereby give you notice that, on or before the day of next, I shall quit and deliver up possession of the house and premises I now hold of you, situate at in the parish of

The date of the delivery of notice, with the tenant's signature and that of a witness, should follow. The landlord's notice to the tenant should be given in similar form. The notice to quit from the tenant may be served upon the landlord by delivery either on or off his premises; but that from the landlord to the tenant should be served upon the premises in occupation. There is no necessity to serve the notice before mid-day—at any convenient time on the proper day will suffice.

In shorter terms of tenancy than that for a year the same rules as to serving notice apply; but the proper term of notice is usually that at which the periodical payments of rent become due a week's notice when the payment is by the week, a month's notice when the payment is monthly, and so on. But the notice given must be from the actual expiration of one period to the end of the following term; for instance, in monthly tenancy, notice must be given at or before the end of the month, to leave at the close of the complete month following. The tenant cannot resign his occupation by a month's notice delivered in the middle of the term.

We must reserve the necessary particulars as to the landlord's remedy for non-payment of rent, and the law as to sub-letting, lodgers, &c., for a future paper.

ELECTROTYPING.—SOLDERING WITH THE BLOW-PIPE.

*Electrotyping.**

Stamped work is executed by means of a stamping-machine, which method is generally adopted in England in producing the various articles to which electro-gilding and silvering are applied. In France, however, the lathe is preferred, as being quicker and more economical.

When an article is not required to be multiplied a sufficient number of times to admit of the expense of a matrix, it is hammered out by men skilled in the practice.

The *furniture* is produced in the following manner:—From models made in wax or plaster a first pattern is cast in iron, which a skilful chaser finishes according to the degree of perfection desired. This is called the model. It passes into the hands of the moulder, who prepares moulds in sand, into which the alloy is poured from crucibles. Thus obtained, the model is cleaned and chased by special workmen. Chasing is a very expensive work, which imparts more or less excellence to the finished article. To abridge this labour, and obtain objects of great perfection, two methods are employed.

* Continued from page 345.

The first can be employed only for moulded work—this is stamping. It is performed with steel matrices and the stamping-machine.

The second is by electrotyping; by which articles of every form, even in *alto-relief*, and others more difficult than moulded articles can be produced. The electrotype skin is filled with brass, which, with respect to solidity and appearance, gives the articles very great value. Then comes the *mounting*, the object of which is to apply the chased furniture to the forms, and secure them by soldering. Mounting demands much care and many precautions; for the elegance of the completed article depends, more or less, upon the taste exercised at this stage of progress.

SOLDERING

Is performed by means of the gas blow-pipe, and by this method the most complicated articles may be produced. The workman can always tell how his work proceeds, for it is constantly exposed to view, which was not the case formerly, when a covered fire had to be employed for the same purpose.

After the soldering comes the trimming down of the seams, and the final smoothing of the article for polishing, which is performed by means of brushes of boar's bristles, which are preferred to buff-leather, as wearing less and rendering the work more uniform. After polishing, the articles are decorated, either by engraving, or by chasing, or enamelling.

DE-SILVERING.

When an article becomes damaged and unfit for sale, or an old article requires to be re-silvered, it is necessary to remove the silver already deposited upon it. To effect this, mix six parts of sulphuric acid and one part of nitric acid. This liquid possesses the property of dissolving silver without attacking the copper. The operation is performed in a hot-water bath at the temperature of 160° Fahr.

In a new de-silvering bath, the copper is so well protected by the presence of the sulphuric acid, that the process has been employed to determine the quantity of silver with which an article has been covered. A series of experiments made upon articles having a known weight of silver shows the value of the process. For the operation to be successful, 1,000 parts of liquid must not absorb more than 25 parts of silver. Beyond this limit the copper is slightly attacked. If we de-silver a plate of copper 16 inches square, upon which a layer of copper $\frac{1}{100}$ths of an inch has been deposited between two layers of silver of fifty grains, the layer of copper interposed completely protects the subjacent layer of silver.

The accuracy of the process has, therefore, no other limits than the approximation of the balance employed.

Ungilding is performed in a mixture formed of sulphuric acid, 10 parts; sea salt, 1 part; nitrate of potassa, 2 parts.

The operation must be performed slowly, and the solution is worked cold, but the results are always less certain than those of de-silvering. De-silvering and ungilding can be performed in a concentrated solution of cyanide submitted to the action of the battery. By inverting the poles, this process is applied more conveniently to articles in steel; for this metal, placed at the positive pole of the battery, is not attacked, while gold, silver, and copper dissolve easily.

PRACTICAL OBSERVATIONS.

By the employment of electro-chemical processes, certain observations, useful to those who practise them, may be derived, the principal of which we proceed to give.

1. The electric current acts in the inverse ratio of the distance: it follows that the nearer an article or portion of an article approaches the anode, the more silver it deposits. It is, therefore, useful to turn this peculiarity of the galvanic current to account, by placing opposite the anode the parts which in the articles to be silvered are most exposed to friction.

2. The density being always greater at the bottom than on the surface of the bath, the deposit of silver is also more rapid. Experience has proved that, upon an article immersed in an ordinary bath, a third more metal is deposited at the lower portion. The only means of remedying this inconvenience, is to turn the pieces during the course of the operation.

STAMPING.

3. In the decomposition of solutions of silver by the pile, the cyanide of silver alone is affected: the silver goes to the negative pole, the cyanogen to the positive pole. The cyanide of potassium set free—less dense than the rest of the solution—rises to the surface of the bath, and determines an ascending current; the cyanide of silver formed on the positive plate is dissolved in the free cyanide of potassium, becomes heavier than the liquid mass surrounding it, falls to the bottom of the bath, and creates a descending current; hence there results in the bath a series of ascending and descending currents, which produce a multitude of small perpendicular streaks on the surface of the articles. To avoid them it is sufficient to render the density of the bath more uniform, by moving the pieces to be silvered.

4. At the same time the silver also deposits in the bath a sub-salt of this metal, which has the inconvenience of causing it to sulphurise more quickly when in contact with the air. To prevent this result, it is useful to immerse the articles, after the application of the scratch-brush, in a bath of pure cyanide of potassium, strength 10 per cent., then rinsing them in water acidulated with sulphuric acid, then in warm water, and drying them; or, which is better, covering them with a paste of borax, warming them slightly at a charcoal fire, and cooling in dilute sulphuric acid.

5. When a piece of plate, even after burnishing, is much sulphurised by long exposure to the air, we can quickly clean it, without in any way altering the burnish and the *mat* that decorate it. It is only necessary to pass it into a bath of cyanide, strength 4 per cent., rinsing in warm water, and drying with a fine linen cloth. Another method, which succeeds better on articles submitted to the scratch-brush than upon burnished pieces, is to pass them into boiling potash, with a bar of zinc in contact.

6. The baths become exhausted at last; that is in consequence of exposure to the air and to the passage of the electric current. A certain quantity of carbonate of potassa and ammonia is formed at the expense of the cyanide, which destroys the properties of the bath. The soluble anode is not sufficient to secure its durability. In order to remedy it, it is only necessary to add cyanide of calcium from time to time. This happy suggestion was made by M. Duchemin, an intelligent workman. By this addition, carbonic acid is precipitated in the state of carbonate of lime, and regenerates an equivalent quantity of cyanide of potassium, without uselessly increasing the density of the bath.

BRITISH COLUMBIA.

THE Pacific Ocean is rapidly becoming a most promising field of Anglo-Saxon and European enterprise. Anglo-Saxon colonies surround it, and Anglo-Saxon pioneers are to be found in every group of its islands. Japan and China, with untold wealth and crowded millions, are slowly opening their gates wider and wider for trade and intercourse. Russia is opening the Amoor and developing Siberia. Already it is proved, by the example of the Sandwich Islands and others, that the islands of the Pacific can produce sugar, coffee, fruits, spices, and other costly merchandise to great advantage. Native labour, guided by European and American skill, has been turned to good and very profitable account. Sandwich Island sugar will compare with the best known, and its "kona" (coffee) will soon be as celebrated as "old Government Java." The fortunes which have been made in the sugar and coffee plantations of the Sandwich Islands during a few years past will, in the next quarter of a century, entice thousands to the numerous islands of the Pacific. Every group of islands is destined to contain its civilised and its civilising community, and the trade and commerce of the whole will rise and spread rapidly. What relation shall we bear to all this growth of the Pacific? This is the question of questions, not only for us, but for our statesmen also. I am bound to declare my conviction that if these colonies are properly managed, we shall, in time, acquire the most commanding position of all. I know it will seem like foolishness to many to suppose that we can even hope to rival San Francisco or California, yet I think it possible, and I will give my reasons why. We have coal and iron—great elements of England's power and wealth—which California has not; we have fisheries and lumber inexhaustible, which California has not; we can build ships, which California cannot, except by paying a freight on timber, which doubles the cost; we have every reason to believe that our gold, silver, copper, and other mineral wealth, is as great as was ever possessed by California, and it is not, in scarcely any degree, exhausted. We have a good agricultural and an

admirable pastoral country—not such as will vie with California, but will, at least, make us independent. California excels in grapes and peaches, but we have the best apples and plums. We lack nothing necessary for our support, and our coal, iron, and lumber give us advantages over California in more ways than one. Coal and lumber are very bulky for the value, and employ large tonnage. The money that would buy a cargo of coal or lumber for a ship of 1,000 tons, could be carried in gold dust on a man's shoulder. This contrast is very striking, if we consider that the four or five millions produced annually in Cariboo, by 4,000 or 5,000 persons, could all be carried in a 10-ton shallop, while a saw-mill employing thirty men, could load a 1,000-ton ship per month, every month in the year. It will prove of immense advantage to these colonies to be able to employ so large an amount of shipping in carrying so bulky an export as coal and lumber, because return cargoes, being less bulky and more valuable, will always be brought to us at minimum freights—a fact to be borne in mind by the promoters of our future railroad across the Continent. Probably half the ships arriving at San Francisco have to leave in ballast, for want of sufficient export from that port.

Again, in possessing coal, iron, and lumber at our hands, we have the means of establishing manufactures here, and in this fact there is ground for great expectations from these colonies. It is when we become the chief seat of manufactures for the Pacific that the vast advantage of our temperate climate will be demonstrated. In the usual order of things, bulky articles will first be made, such as iron and brass castings and machinery, agricultural implements, wagons, carriages, household furniture, leather, &c. We have an excellent sheep country. At this moment there could scarcely be a better business than a blanket factory here, wool costing two-thirds of the price with you, and blankets fifty per cent. higher, and the Indian consumption enormous. At present a vital objection to manufactures here is the high rate of wages, but in time this will correct itself.

On the other side of the Pacific Ocean lies a country with 300,000,000 of labourers, who are happy if they can earn from two to three dollars per month, and who are ready to emigrate in countless thousands if they can get from five to eight dollars per month. They are a plodding and industrious race—not so strong nor so effective as the European in heavy work, or in work requiring judgment, but quick in learning, and unwearied in performing or repeating a dry detail of any work. The Chinaman is pre-eminently calculated to supply our factories with hands, to do what the women and children of England have had to do. In the future manufacturing systems of this country, the white man will be the manager, director, and man of skill, and Chinamen the operatives.—*Times Correspondent.*

Amusement and Recreation in Working Men's Clubs.

BY THE REV. H. SOLLY.

While it is quite certain that Amusement (including in that term social intercourse) is the first thing to be provided for by these Clubs, and that improvement of various kinds (mental, moral, and pecuniary), is the second, it is a point of paramount importance for working men and their friends to see how they can make the second result grow naturally out of the first.

This is not difficult, when we once get on the right track. A beneficent Creator has bound together in natural connection, and in beautiful harmony, things that are pleasant and things that are improving; has made the universe on such a plan that, if we attend to obvious principles, we shall derive immense enjoyment from learning what there is in it, as well as from using our own powers to add to its beauty, its wonders, its conveniences and joys.

One way, however, in which people who know a little have tried to teach it to those who know less, has been used for years at Mechanics' Institutes, and more recently at Working Men's Clubs, in both cases, for the most part, with signal failure. I refer to *Lectures*—but especially to lectures intended to convey knowledge or to promote improvement. Of course there have been various exceptions. I speak only of the general rule. Lectures, generally, are not well attended. No surer device can be adopted for securing a bad attendance of the members of these Institutes and Clubs than to announce the delivery of "A Lecture," unless some very gifted orator or unusually attractive subject is announced also. It has been found, however, that the exhibition of diagrams, dissolving views, &c., materially helps to draw or retain an audience. It is a great help, of course, to a tired or uneducated person, to have some illustration to look at, while striving to attend to a verbal description or statement. In the same way, also, experiments in chemistry, or with an electrical machine, air-pump, &c., materially aid their efforts.

But there is a large class of extremely interesting subjects, on which it is very desirable that working men should get information, but which cannot be illustrated by anything but diagrams or specimens—perhaps not at all. Most literary and historical subjects come under the latter head, and descriptions of the structure and functions of the human body, of animals, of famous cities, fossil remains, &c., under the former. Now, an admirable mode of drawing an audience to listen to selections from our noble English literature has been the "Penny Readings," which have achieved such national success, and been productive of such remarkable benefits. That success has been mainly promoted by the introduction of music, and especially of singing, between the readings. The latter alone have sometimes been highly popular; but, as a general rule, the songs have been found needful to win or maintain this popularity, or, at all events, to accomplish the most signal and *repeated* success. Here, then, we have an instance in which no ordinary benefit—viz., an acquaintance with and delight in English literature—has been connected in a perfectly legitimate manner with amusement, so that large numbers of people who were at once far too uneducated and too wearied to care to come to lectures on English literature, have been both benefited and highly amused by a judicious combination of readings and song.

Now, the point I am coming to, guided by these facts, is that we may avail ourselves to a large extent of the marvellous power which music possesses to gladden and refine the human heart, for the purpose of procuring an audience to listen with attention to other matter no less interesting, when pleasantly handled, than extracts from poets, humorists, and writers of fiction. Having prepared what would formerly have been called *a lecture*, on "The Hand, the Hoof, and the Wing," founded on Sir Charles Bell's very interesting Bridgewater Treatise, I consulted with the committee of one of our London Clubs as to the possibility of getting their members to listen to it. We were all agreed that it was very important to offer them something of an instructive or improving character occasionally, by way of variation to the perpetual round of mere amusement previously going on in the Club, and especially at their weekly entertainments; but we were equally agreed that to announce "a lecture" would be to ensure empty benches. Accordingly, the committee, at my suggestion, applied to our tuneful friends, the ever-willing-to-oblige Camden Town Club choir, and got their consent to come and sing a few songs, and give two or three recitations, on the occasion of my performance. We got a bill printed, therefore, to the effect that, "At the next Monday evening entertainment," I was to give "a description of the Hand, &c.," "illustrated by diagrams, and a few (bony) specimens, interspersed with a few songs and recitations by members of the Camden Town Working Men's Club." The plan proved successful. The "entertainment" commenced with two or three songs and a recitation, given in the able and pleasant style with which many of our London clubbists are familiar; then came the first part of my "description," which consisted mainly of what would, perhaps, have been considered rather dry stuff, if taken by itself (though enlivened occasionally by an anecdote or a joke, if it came handy), but which the previous amusement had sufficiently attracted and braced my audience to swallow contentedly—nay, even cheerfully. About twenty-five minutes of this work was a sufficiently long trial of their patience; but before they were thinking how to get away, I suspended my descriptions of comparative anatomy, and the chairman again introduced the choir. Two or three more songs or recitations, and then I concluded my labours with about fifteen minutes' additional description, and ten minutes of exhortation to make "the many members in one body of their Club work harmoniously and zealously together for the common good."

This experiment having worked well, I have repeated it at three other London Clubs with similar results. Miss Wallington kindly gave some of her admirable recitations when I went to the Southwark Club, and the members of the other Clubs provided the musical part themselves. I believe that, however comical the thing looks at first, there is no reason why *many* "lectures" should not be divided into two parts, with songs and recitations between, nor why *all* such useful exercises should not be preceded and followed by musical and literary amusement. We have often urged that the members of Working Men's Clubs must have some other and better excitement offered them if you would withdraw them from the public-house; but if that excitement can occasionally consist of blended amusement and instruction, you are not only doing the members double good at the time, but you are unfolding the higher elements of their nature and character, and making the Club a source of permanent blessing. Penny Readings will always, I trust, maintain their ground, and preserve their present high character; but everything human has a tendency to degenerate, and all human enjoyments require variety. I have heard more than once that these Readings were losing their hold upon the public in particular localities, and required a larger and larger infusion of the comic element (bordering even upon what was coarse) if they were to continue to attract. Much that could be given in the shape of historic and scientific description, would be quite as popular and fascinating as extracts from our best authors, if it could be varied, as the "Readings" have been, by music, &c.; and many persons who would have given a lecture a remarkably wide berth, would come for the sake of the songs, intending patiently to endure the "description," going away surprised and delighted to find, at the end of the evening, how much they have been at once instructed and amused. A striking illustration of the successful working of the above plan was recently afforded at the same Club at which I first tried the experiment last winter. Elihu Burritt had kindly engaged to give a lecture there on the "Charities of London," but when the time came for commencing, there were not a dozen people in the hall, nor much prospect of more coming in, though the rest of the Club-rooms were well filled. But, according to arrangement, the piano struck up a lively air; this was followed by a song or two; the hall rapidly filled, and Mr. Burritt had a good audience to begin with. Many, I believe, only meant to remain a little while, and then to go back to their games, &c., but once there, they soon became interested in the lecture, and fascinated by the lecturer's style and manner. Scarcely a person moved till he had finished, and vehement applause told how successful the attempt had been. Songs concluded the evening, and all felt how good it had been for them to have heard what they did, instead of the whole evening being occupied in their ordinary amusements. In this, as it would be in many other cases, the lecturer did not wish to divide his lecture—which, in fact, would have been an unsuitable proceeding; but in general either the subject would admit of the variety, in the middle, of songs and music, or the interest would be sustained throughout to the end. Of course, much depends upon the lecturer being able to say what he has to say in a pleasant, popular way, especially if the subject be a scientific one. But in all cases, however excellent the plan, personal qualities, of course, are a main element of success. Music, nevertheless, is a mighty lever for raising and improving the condition and character of our race, as well as for giving rational enjoyment. Let us apply it in the manifold ways which Working Men's Clubs, among other agencies, abundantly afford.

While, however, we cannot be too strongly impressed with the need of providing entertainment and instruction in Working Men's Clubs and Institutes, it is equally necessary to remember that many men will be far more interested in measures for promoting the comfort and pecuniary well-being of themselves and their families, than in entertainments or mental excitement of any description. The latter will almost always be welcomed by the great majority of working men, and be of value not only in itself, but also in attaching them to the Club; but with a considerable number of them amusements will always be a subordinate affair, and their connection with some Provident, Friendly, Co-operative, or similar society will be the sheet-anchor to hold them fast. The *Kentish Town* Club is a striking instance in point. This Club has had a hard struggle for life, owing to various causes, but early in its career some of its able and zealous managers formed a Provident Loan Society, Coal,

Clothing, and Christmas Provident Clubs, and I may here add that it is now proposed to form the Coal, Clothing, and Christmas Clubs into one general Co-operative Society, for the purpose of purchasing all domestic articles at wholesale prices. Those societies have been very useful to the members, and highly valued. Hence, when the rest of the members of the Club fell away, these continued staunch, and resisted every proposal to break up the Club, which, they said, would just ruin their Provident Societies. Thus, standing firm, they have been enabled, with the seasonable help of their honorary members, to exist through periods of great depression, and, I think, they will now be able to last till, avoiding former errors, they have won over to their side a large number of the working men of the neighbourhood.

A somewhat similar and important illustration comes to us from the *Hull* Working Men's Club. The secretary says in his "Return," kindly furnished to us early in this year—"Our Club now is in the possession of the Co-operative Store, both being on the same premises, and is managed by the committee" (of the Club). Then, in answer to the question, How far is the Club self-supporting? he writes—"Since we have had it (the Club) in connection with the Co-operative Store—six months—it has supported itself. *Previously it was losing £1 weekly.*" I have often had to dwell on the great mutual benefit which Clubs and Co-operative Stores may confer on each other, and it is worthy of remark that many men whom no amount of ordinary amusement or mental entertainment (still less, of course, anything in the shape of mental improvement) would induce to leave the publican's fireside, have abandoned it and, by degrees, taken altogether to better ways, in consequence of having joined a Co-operative Society. They will come to the shop and lounge in the back parlour, if fortunately there be one, and talk about "the concern" in which they have acquired a definite stake, with an interest that lifts them out of the old rut for a time, and gives the chance of interesting them in other things also.

But, *per contra*, a very promising Club has been brought to death's door, mainly, I believe, through the best men connected with it forming a Co-operative Store, and having all their time and energies absorbed in its management, so that the poor Club was deprived of its natural and fittest leaders, fell into incompetent hands, and has gone into a condition from which, I am afraid, no power can rescue it. Let our friends at Hull and elsewhere note this melancholy catastrophe, and take care to secure sufficient *managing power* for both their valuable undertakings. Working men's enterprises so often fail, because of the very limited time at their command. The best men to manage any society naturally have their hands over full, from the number of important and responsible duties pressed upon them, as a consequence of their having won the confidence of their neighbours.

THE HARTFORD WORKS.

Yet larger is the establishment of Messrs. Platt Brothers and Co., at Oldham, known as the Hartford Works. In it more than 5,000 men and boys are constantly employed, to whom at least £250,000 are paid each year in wages alone. Its various forges, foundries, workshops, and yards cover twenty acres of ground, and consume each week about 500 tons of coal and 150 tons of coke, which, by help of fifteen steam-engines, with an aggregate power exceeding that of 2,500 horses, convert some 450 tons of iron every week into machinery of various sorts. The iron reaches the works in the crude state to which it is reduced by the blast-furnaces. It is puddled and brought into a malleable condition before being conveyed to the smiths' shop, there to be submitted to an iron-cutting saw capable of revolving a thousand times in a minute, and passing in each revolution through a trough of cold water, to prevent it from becoming too hot by friction with the metal. The iron bars thus cut into the proper lengths, are next pressed between revolving rollers, which give them a perfectly smooth and uniform surface; then they are conveyed to the turning and fitting shops, "which," we are told, "for extent and completeness stand unrivalled in the world. On the floors of the buildings set apart for these processes, hundreds of turning-lathes, and of planing, shaping, slotting, boring, and screw-cutting machines are to be seen at work. In one room we see a planing-machine with a bed large enough to hold one-half of the framework of a large power-loom, the cutting-tools of which are so adjusted that all the portions of the frame which require planing are acted upon at one time, while in another we find a shaping-machine, manufactured at great cost, devoted to the production of a tiny bracket. One turning-lathe will be found reducing the face of a huge cylinder—the chisel, as the cylinder turns slowly round, paring the hard metal with as much apparent ease as though it were chalk, while at another an active lad is turning off small iron screws by the gross." The different parts of the various machines that are to be produced, are forged and shaped in different rooms. They are finally taken into the fitting-up rooms, there to be put together and prepared for distribution to the wholesale dealers and shipping-agents. All sorts of machinery are made in this vast establishment, but its chief business is in the construction of appliances for cotton and woollen manufacture. It is calculated that in it could be produced each week the entire fittings and furnishings for a mill of 20,000 spindles for preparing and spinning either cotton or wool, as well as for a weaving-shed of 200 looms, of which the yarn thus manufactured is to be made into cloth.—*London Society.*

THE COMING DAY.

Hurrah! hurrah! the night is past,
The dawn is in the sky at last—
The dawn of love—the morn of peace,
When hate, and strife, and wrong shall cease,
And earth with smiles of heaven shall glow,
Lit with the dreams of long ago.

Oh, happy morn! oh, blessèd day!
Whose sun shall chase our fears away;
Shall light the dark, and burst the chain
From aching hearts that plead in vain,
And into crowns of glory turn
The thorns that pierce—the tears that burn.

Joy, joy to him whose eyes shall see
The grandeur of that day to be!
That ripened splendour in the East—
When hungry souls shall rise and feast,
And, God-encouraged, land with land
Shall walk as brothers hand in hand.

The spear shall be the pruning-hook,
The sword, the teacher and the book;
The battle shout shall be the cry
Of every evil doomed to die:
And good alone shall nestle here
In that great day whose hour is near.

Matthias Bare.

*The Moral and Social Aspects of the Temperance Movement.**

It has sometimes been ascribed to the advocates of Temperance as a weakness that they associate the exclusion of alcoholic liquors with the dawn of a millennium, not only of sobriety, but of every grace and virtue: but we are persuaded that such a representation is unfair. They say that the effects would cease with the extinction of the cause; and from this common-sense axiom they draw the conclusion, that by universal total abstinence from strong drinks society would realise all the benefits involved in the extinction of drink-caused pauperism, crime, and sensualism of every grade. This conclusion has been disputed, on the ground that some other form of animal indulgence would take the place of drinking, and, perhaps, one more injurious. But the advocates of Temperance are justified in refusing to fight so aerial an objection, which is unsupported by historical analysis, and contradicted by the effects already observed—and which could be just as pertinently alleged against every means of effecting a removal of our national intemperance. It is also quite a gratuitous assumption that some other intoxicating agent, as prolific of immorality, would be discovered. Opium is often named as a drug resorted to by abstainers from alcohol, but the charge has hardly ever been sustained in individual cases, and is notoriously false as applied to the Temperance community. Whatever, too, may be its physical effects, in a moral and particularly a crime-producing view, opium cannot be compared with the spirit of the still. Loose writers have at times appealed to the vices of the Turks and the cruelties of the Hindoos as evidence that sobriety may co-exist with immoralities of the deepest dye; but the appeal is pointless. Both Turks and Hindoos have become extremely corrupted, as to the use of alcoholic liquors, by European associations; and it is well known that the Turks, among whom the highest moral characteristics are to be found, are precisely those who remain faithful to the mandate of the Koran against the use of wine. The conduct of the Sepoys during the mutiny was exceptional, and their worst cruelties were generally connected with the use of arrack, or bhang. Indeed, were no other differences to be considered, those of religion and superior civilisation on our own side would make all attempts at a parallel ridiculous. It is rather to our discredit that, with such immense advantages, our moral state should, on the whole, be so imperfect; and if the predominating cause of this failure is brought home to "the drink," the Temperance advocate cannot be accused of fanaticism, in predicating a very great and beneficial change as the result of his principles, were they nationally adopted. Even short of a national adoption, he can point to the success of the experiment on every scale, large and small. In Ireland, as before remarked in reference to economy, so even we may observe in regard to morals and social improvement, the transformation was as complete as could be imagined. In America the Washingtonian reform of 1840-2, by which 300,000 drunkards were reclaimed, was like the fall of a teeming rain on an arid soil. In Wales similar effects have been produced, and in no case have the good results been known to abate while the efficient cause retained its vigour. In many parishes, of both England and Scotland, where no sale of intoxicating liquors is permitted, by the refusal of the landowners to have any house licensed, the moral and social condition of the people contrasts favourably with that of the inhabitants of other parishes where no such restrictions are imposed, even though the parishes under the two systems have their boundaries side by side. Could a similar comparison be instituted between large towns—could one class altogether illustrate the effect of total abstinence, and the other class continue to exhibit the effect of common drinking—it can scarcely be doubted that scepticism would be compelled to admit a difference which, in the absence of such a series of comparisons, it is vain to deny. The abstainer, however, can plead with reason that many of the moral and social advantages incident to his system are overlooked and qualified, especially in domestic training, by the interfusion of classes and the exposure to evil influences from the opposite system. But sufficient is seen and demonstrable to show how much society would gain by an adoption of the one system in place of the other. All that strong drink ever does to sow the seed of an unnatural vice, to excite the lower appetites, to fire the passions, to induce extravagance and idleness, and thence poverty and want—all that it does to increase crime, and feed the grosser vices that prey on soul and body—all that it does to turn home into hell, and blast the hopes of childhood—all this would cease, if the Temperance Reformation could be consummated; and were it to cease, who doubts that happier days would dawn upon the England we love so much?

All social reformers are likewise forward to acknowledge the connection of social and moral progress with conditions of sanitary surroundings and natural comforts. The influence of Temperance in directly ministering to these conditions may, therefore, be set down to its further credit as an instrument of moral and social elevation. Its wonderful powers of usefulness, when earnestly plied, have been fully proved; and its zealous advocates cannot be blamed if they look back with wistful eyes to the greater blessings which a more general employment of the same agency would confer upon the nation.

* Concluded from page 323.

Master and Apprentice.—In a recent action, "Rayment *v.* Winton," in the Court of Exchequer, for an alleged breach of covenant, the declaration stated that the plaintiff's son-in-law had put himself apprentice to the defendant to learn the art, trade, or business of a builder, ornamental painter, and decorator, for a period of five years, and that the defendant thereby covenanted to teach the apprentice in the said art, trade, or business, by the best means in his power, but had neglected and made default. The defendant, by his plea, stated that at the time of the alleged breach the apprentice would not be taught, and by his own acts hindered and prevented the defendant from teaching him, and thus caused the breach. The Court sustained this plea. The apprentice's willingness to be taught was, from the necessity of the case, a condition precedent to his being taught; and as the master's covenant was to teach by the best means in his power, and the apprentice had put it out of his power to teach, he could not be called upon to perform an impossibility.

MONEY PRIZES,

TO BE COMPETED FOR BY

WORKING MEN.

IN our next Number an acknowledgment in detail will appear of the Essays which have been sent in for competition for the Twenty Prizes, Ten of Five Pounds each and Ten of Three Pounds each, offered by Messrs. CASSELL, PETTER, and GALPIN.

"ALL LABOUR IS SACRED."—*Carlyle.*

Working-Class Policy.

WHEN an eminent ecclesiastical rhetorician wanted a simile, which should illustrate unappreciated profusion, he fixed upon water and words: water, whose plentifulness enables us to offer it freely, and words which, in the shape of advice, are given with greater bountifulness. Notwithstanding this subtle warning that advice may be tendered in futile copiousness, we shall venture a few sentences upon what we may call working men's policy. In so doing we invite the careful attention of working men to the subject, which, obscure and unpromising as it may at first seem, bids fair at no distant period to become one of paramount importance.

It is a new thing, and a great thing, to find that working men have reached that stage of progress when they have conceptions of policy. We are distinctly persuaded that their ascendancy in the social scale and in personal prosperity will be secured when they come to act on general principles—when they place before themselves great objects, and come to an understanding among themselves as to the methods to be pursued to accomplish them. All their failures in association, all their apathy in compassing unity among themselves, arise from not having given thought sufficient to the kind of policy the best calculated to promote their just ends.

Many think that policy means mere craftiness, and will have nothing to do with it. If it means this, they are right in having nothing to do with it. But it does not mean this. It means method of procedure; it signifies the selection of honourable means for the attainment of honest ends. Everything intelligent is really regulated by a policy of some kind. He who speaks grammatically, speaks with policy, for grammar is but the policy of speech. The arithmetician acts on policy, for arithmetic is but the policy of calculation. The mathematician acts on policy, for geometry is the policy of determining magnitude. The very laws of music are but the policy of melody, just as law is the policy of liberty, and order the policy of progress, and justice the policy of security. The fact is, that man is ignorant who does not understand policy, and is an hourly blunderer who does not act upon it. Nobody objects to policy except those who do not know what it means, and who mistake it for something else.

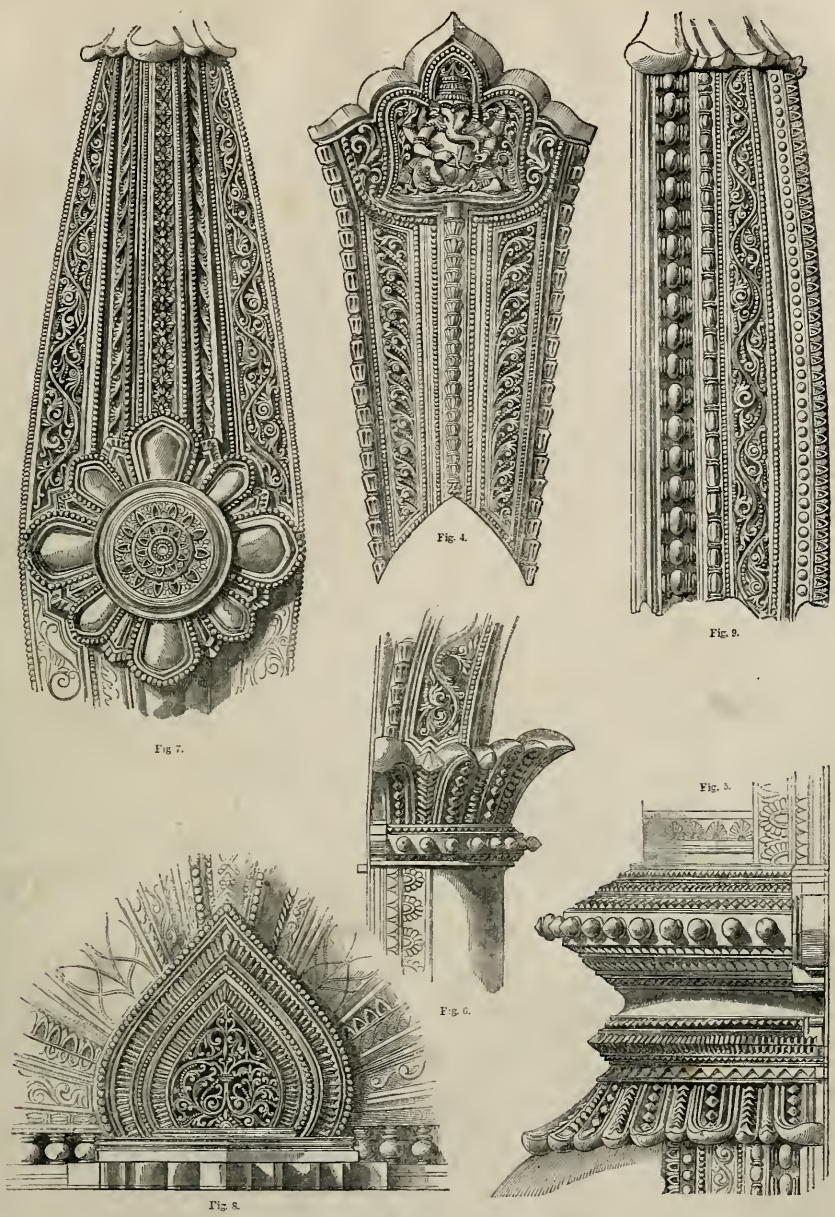
In the days when the working class thought of physical force as a means of political elevation, that was their policy so far. Even that stage indicated that they were acquiring ideas of policy, though in this case erroneous, peradventure. Now they begin to see very generally that it is by unity, by intelligence, by habits of providence, by use of Co-operation, and similar means, that their best chances of success appear. The working class, therefore, are settling down into chosen methods of procedure for the improvement of their condition. This is policy.

Temperance, every thinking man now knows, is the policy of health; regulated exercise is the policy of strength; economy is the policy of wealth; truth is the policy of manliness, as the liar is ever a coward or a knave. But men who can now well discern principles of policy for themselves, fail to discern them in others. A curious instance has lately occurred in a London Trade Society, mentioned in the public prints. The United Trades have been justly active in procuring an amendment of the Masters' and Workmen's Act, with a view to equalise the legal position of workman and employer in cases of breach of contract. Lord Elcho has made himself instrumental in procuring a Parliamentary Committee of Inquiry into the operation of the existing Act, and will, in due Parliamentary course, be the Chairman of the Committee. This office implies great labour, and responsible attention to the question. To undertake this implies good feeling towards the men seeking the inquiry, and his lordship not only commits himself to the necessity and justice of the inquiry, but commits also, to an appreciable extent, gentlemen with whom he usually acts in Parliament, who are not politically very favourable to the working class. But the trades societies have, it appears, objected to Lord Elcho being chairman. This does not seem a sound act of policy. Lord Elcho is more likely to do justice to the working class in social matters than a chairman politically favourable to them. Nothing is more common than to find men illiberal in one thing, liberal in the very opposite. Men who will withhold political power, will accord very readily social privileges, with a view to satisfy them and render them contented. A Tory, for instance, is far more likely to have paternal sympathies towards working men than a Whig, and a Whig more so than a Radical. It seems curious, but it is quite true, and as common as it is true. The Ten-Hours Act, and many features of the Factory Acts, which are beneficial to the working class, would never have been passed but for the aid of Tories. These concessions might have been prompted by the antagonism of the landed interest to the factory interest. With this we have nothing to do. We do not justify it, nor apologise for it; we only explain it. We look upon the question purely as one of policy. The Whig thinks the people ought to take care of themselves, and, therefore, would give them rights to enable them to do it. The Radical is still more favourable to the independence of the people, and would give them equal rights, and is rather apt to leave social rights to develop themselves as they can; and many Liberal constituencies are rather inimical to them. Now, the right of self-help is a higher gift than many acts of paternal kindness; and so the motive of those who give least may be more estimable than that of those who give most. But those who will give most of what you want are not to be lightly set aside. In matters of policy we think first of how we are likely to get what we most want, or profess to want, and accept the services of those most likely to give them. If, while professing to amend an Act of Parliament, we are most anxious to resent political slights, and retaliate upon members of Parliament with whom difference of opinion exists, that may be amusing, exciting, or even useful; but it is pursuing one object while professing to seek another. In the case we have named, it is converting a question of legal right into a political disputation. This may be commended by many reasons at this time, but it is an example of what is *not* policy. The late Mr. Cobden would never do this. His great success was owing to his seeking clear objects and accepting the aid of all who would promote them, and in never mixing up two distinct things together. In politics, as in other affairs of daily life, doing one thing at a time is true policy. But this subject is a wide one. We scarcely open it; we do not exhaust it. An illustration of it lay near at hand, which it seems useful to offer. If our remarks cause the question of methods of procedure to be thought over by working men, it will lead, whether to this view or that, surely to larger views; and with width of view comes soundness of view, and that is the main thing.

GYMNASIUMS WANTED.

LIVING close to a great thoroughfare in a northern district of London, we have often noticed, with pain and surprise, the large number of wayfarers who are "deformed, unfinished," and either crippled by weakness, want of care in infancy, or by following unhealthy trades. Many have one or two club feet; others are bent in the limbs on one side; there are stiff limbs, which do not act so well as the artificial ones of clever makers. Many are deformed and stiffened by attacks of rheumatism, and others by paralytic and nervous causes. The bandy legs and rickety state of very young children might be, to a great extent, prevented, by attention to proper air, food, and clothing supply; and in other ways much of the evil referred to might be lessened, by surgical attention to children when in their younger years. Notwithstanding there are facilities afforded for the cure of these imperfections, not only in the Children's Hospital, in Great Ormond Street, but in other of the metropolitan hospitals, where often a simple and not very dangerous operation, with a little care, will prevent the early close of life, or the passing of one in a lame and crippled state; still, the opportunity is neglected, and in course of time the deformity is still further confirmed by the sufferers being put to some sedentary employment. This is a matter which requires more thought than has been generally devoted to the subject; and we believe that, if it were better known how easy it is to get assistance of the very best description at St. Bartholomew's and other hospitals, and also the use of splints and apparatus of different kinds, but a tithe of the lame would be seen in the streets of our large towns. A considerable number of the cases of deformity which are far too frequently met with arise from accidents, but some are brought upon youths who are sent, at the ages of from thirteen to fourteen and fifteen years, to trades which, in course of time, to a greater or less extent, make the limbs lose their fair and right proportions, and, in addition to discomfort, cause much damage to health. In Sheffield, Birmingham, and some other towns, where many persons are employed in the grinding, polishing, and finishing of tools, a trade which requires both men and women to stand or sit for many hours together in one particular attitude, the muscles get set in a form similar to that which the workpeople stand or sit in when labouring at the bench.

In Clerkenwell a considerable amount of this kind of



ORNAMENTAL DETAILS OF THE INDIAN BINA, OR GUITAR.

deformity may be noticed, particularly amongst those who are employed in some branches of the gold and silversmith and jewellery trades. There may be seen lads, of seventeen or eighteen years of age, who work at the polishing of gold and silver ornaments, whose limbs have become like the Sheffield grinders, of unnatural and unhealthy forms, and this kind of deformity comes more quickly than many suppose, and extends to various employments. The long-established letter-carrier or deliverer of newspapers gets a form of arm and shoulder which is still to be noticed when he has nothing to carry or deliver. By his particular gait, any one can distinguish a tailor or a shoemaker in the street; and clever detective and other skilled officers of police can, by certain indications, guess whether or not a man is telling the truth respecting his past pursuits. It is a great pity that crippling of this kind should be allowed, for there can be no doubt that facilities for gymnastic exercises, used properly and in sufficiently early time, would to a great extent counteract the effect of most sedentary trades. Gymnasiums, which could be easily accessible in both winter and summer, at a small cost, would be of the greatest service.—*Builder.*

*Indian Ornamentation.**

A BINA, OR GUITAR.—DETAILS OF THE ORNAMENT.

HEAD OF THE INSTRUMENT (FIG. 1, PAGE 322).

Fig. 4. *Trilobate medallion in ivory, perforated, on a gold ground.*—Ganesa, God of Wisdom, Destiny, and Marriage, represented with the head of an elephant, was the son of Siva and Parvati.

Fig. 5. *Ornament terminating the lower portion of the neck, seen in profile.*—The upper part is composed of seventeen ivory cloves, and the lower part of nine palmettes, carved in wood, painted yellow, encircled by a double red line. Between each palmette is a slender palm, streaked with green colour. The small vacant space between the two ornaments is decorated with striated circular bands, alternately red, yellow, and green.

Fig. 6. *Ornament placed below the head of the instrument, seen in profile.*—This is identically similar in material, workmanship, and colouring to that described above. The only difference consists in the position of the palmettes, which are upright, instead of being reversed.

TOP OF THE FINGER-BOARD (FIG. 2, PAGE 322).

Sculptures in ivory, perforated, upon a gold ground.—Two Apsaras (celestial nymphs), of whom Rama is queen, and who charm by their dancing in the paradise of Indra, God of the Air and the Seasons. This subject is surmounted by an ivory bow, over which passes the four strings, which are wound upon the pegs.

Four Gojris, companions of the infancy of Krichna, sustain a tree, the branches of which envelop this deity. Beneath, Gandharvas, companions of Indra, are dancing.

Fig. 7. In the sonorous portion of the instrument (Fig. 1, page 322) the middle zone is decorated throughout its entire length by three bands

* Continued from page 322.

of carved ivory, separated from each other by small arabesques, painted on wood. In the middle, and surrounding a medallion of carved ivory upon a gold ground, are eight palmettes in painted wood—four of which are upon a red ground, surrounded with a triple milled yellow line, and four upon a green ground, with lines similar to the first.

Fig. 8. The zone, which occupies the middle of the back of the instrument, has on each side a large band of ovoidal form, in wood, painted red, decorated with light yellow interlacings. These two zones are environed by a running ornament in carved ivory (Fig. 9) terminated by a row of ivory balusters, detached from each other, and upon a gold ground.

The ornament which terminates the decoration of this instrument is formed by a small bas-relief in ivory, of ogival form, perforated, upon a gold ground.

Children in the Black Country.

"A Staffordshire Lad," writing to the *Pall Mall Gazette*, states that notwithstanding the success which has attended hitherto the introduction of the Factory Act, any proposal to extend its application to other districts elicits a storm of opposition both from the ranks of capital and labour. The Black Country is a case in point. Here the mines, forges, and workshops abound with children, many little more than infants, who, for a miserable pittance, are deforming their bodies, corrupting their minds, becoming lost in ignorance and crime. Few districts in the country have furnished more revolting instances of juvenile depravity. The commercial progress of the district has also been to some extent retarded by the poor mental and physical condition of its workpeople. Both these facts are traceable to the same source; yet the Government proposition, urged by Lord Lichfield, to extend to the Black Country the Act which has proved so beneficial in other parts of the country is strongly opposed, not merely by "the unthinking multitude," but, strange to say, by gentlemen of influence and position in the district. At such a moment, a few facts as to the condition of the little children of the district, which have come under the observation of one who has spent much time among them, may be interesting.

Standing on the venerable ruins of Dudley Castle, a complete panoramic view is obtainable of that part of South Staffordshire and East Worcestershire not inaptly termed the Black Country, a district extending some six or eight miles in every direction around that pile. The population of the Black Country exceeds half a million, of which number one-third are engaged in the mines and brick-fields, one-third in the iron-works and furnaces, and the rest in the miscellaneous metal and hardware trades. With the exception of the mines, which are already under Government supervision, children under the age of thirteen are engaged more or less in all these branches of industry. The approximate number of these "little hands" has been computed as follows:—Furnaces, brick-fields, &c., 1,000; iron-mills and forges, 1,000; hardware and metal trades, 3,000; making an aggregate of about 5,000.

The employment of these children at the furnaces is called "box filling," or loading the trucks which convey the material to the furnace. It is an out-door occupation, requiring considerable strength and endurance, and engaging them in turn by night as well as by day, with no intermittent respite on Sundays, except in some few instances. The hours of labour are from 6 a.m. till 6 p.m., and from 6 p.m. till 6 a.m. respectively for the day and night set of these boys, who work as long as their fathers. In this case, however, beyond the fact that children so young are employed at all, there is nothing specially to complain of.

In the mills and forges, boys of all ages, from eight and upwards, may be found, amid the labyrinth of machinery and the coils of heated iron, engaged by day and night in tugging long red-hot seething bars. Their activity is very great, owing to the nature of their work, which requires rapidity of movement, and contrasts strangely with their otherwise jaded and worn appearance. In addition to the labour of dragging along the iron, each of these little fellows has to run, in short stages, a distance of more than eleven miles every day, in an oppressive atmosphere, thick with dust and steam. Owing to the quick and uncertain movements of the hot iron bars in their passage through successive rolls before having time to cool, the occupation of these boys is attended with some danger, a serious burn being an almost every-day occurrence. Standing in the midst of an extensive forge a few years ago, I was alarmed by a cry of terror at the farther end of the works. There was a general rush to the spot, and I shall never forget the horrible and sickening sight that met our view. A large rod of seething iron, in coming from the rolls, had somehow twisted aside, and had literally pierced through the body of a little fellow some ten years old. For awhile the roar of the machinery was suspended, and two or three brawny puddlers carried the hapless creature home; but when the first thrill of horror had passed away the wheels were again set in motion and all went on as before. The lives of these boys are almost entirely spent in the forges, except the hours allotted to sleep. They have their meals there, and in the snatches of leisure it is their playground. In most of the works is the arm or basin of a canal, the water of which is kept in a state of chronic fever, and in which, despite its inky colour, they delight to bathe both in winter and summer. So constant are they in their ablutions that they often come out parboiled, like a washerwoman's thumb. Some of the proprietors of these works have provided night schools for the instruction of the children in their employ; but as a rule they are in mind and body alike neglected, and the densest ignorance prevails. They have no home training, most of their houses being locked up all day, the parents and all the children being out at work; and returning home fatigued at night, nothing but bed or a carousal in the "Fox and Dragon" is acceptable. Returning home late one evening, I saw two little children, a boy and girl, lying asleep upon a doorstep, which proved to be that of their own home. On awaking them, they told me they were waiting for their mother to come out of the neighbouring tavern and open the door. They had no father, and had been hard at work all day. The boy worked in a forge, the girl in a foundry, and the mother in a japanning factory, and though thus separated all day, there seemed no bond of affection to bind them when they met together.

West of Dudley is a strange, wild region known as the "nailing district," composed of scattered hamlets, to all the houses of which is attached what appears to the stranger a blacksmith's shop. The manufacture of wrought nails is, and has been for a century and more, the great staple industry of the district. It is carried on by the nailers in their own houses. In few trades of the district does the employment of women and young children assume a more objectionable form than in this. The women seem to have lost all traces of the modesty of their sex, and from childhood are addicted to swearing, smoking—resembling as far as possible the other sex in their habits and deportment, even to the wearing of their coarse flannel jackets. They mostly marry very young, often at fourteen, and seldom later than eighteen or twenty. With such women for mothers, it is not difficult to judge of their children. From tenderest ages, often from five or six years, they are trained to that round of labour in which their lives are doomed to be spent. The first stage is "blowing the bellows," and next they are taught to forge the smaller kinds of nails. The hours of labour are dreadfully prolonged, often exceeding sixteen hours per day; the rate of remuneration is very low, and the homes are consequently wretchedly poor. Entering one of them lately, I saw the father, mother, and eight sons and daughters, all toiling in a small, ill-ventilated, dirty hovel. It was growing late in the evening, and I inquired, "Is it not time to cease your day's work?" "Oh, noa, maister," rejoined the mother; "we've a noit's work afore us yet, or there'll be no bread o' the loaf o' Sunday." It was Friday night, and it was, as I learnt, a practice to work from Friday morning until Saturday afternoon, without having more than short snatches of rest for meals. While I lingered, a little fellow, who could not have been more than eight, fell from his work apparently exhausted, but his father, on observing it, threw at him a hammer-handle, telling him, with an oath, to re-commence his work. He took no part in our conversation, having, like his two eldest daughters, a short pipe in his mouth, which seemed to him and them "the calumet of peace."

This is by no means a solitary case. Hundreds of such instances are to be found of little boys and girls, just emerged from babyhood, ill-fed, ill-clothed, and over-worked, trained amid vulgarity and vice, and in the densest gloom of ignorance. Were it not for Sunday-schools, I shudder to think of the future of these hapless children. Their lives could only be compared with those of the "heathen in his blindness," on whose behalf Exeter Hall is pleading so eloquently during this month of May. I visited a Sunday-school in the nailing district a few Sundays ago, and found there a multitude of these little "Christian savages." They were lustily singing a hymn as I entered which is very popular in the district, rather, I suspect, because it goes to a lively tune than because many of the children can heartily appreciate the sentiment of the words:—

> "I thank the goodness and the grace
> Which on my birth have smiled,
> And made me in these Christian days,
> A happy English child.
>
> "I was not born a little slave
> To labour in the sun,
> And wish I were but in the grave,
> And all my labour done."

A sad feeling came over me as I looked upon the crowd of wan, pale faces and worn frames, and compared that scene to the burden of the song of praise, and I could not help wishing from my heart that the contrast was somewhat more striking between "a little slave" and these "happy English children."

In other branches of the hardware and metal trades the evils of child labour equally abound, especially in the foundries, japan-works, and tin-plate factories; but, as a rule, they are less aggravated in the large establishments than in the smaller workshops.

Space will not, however, allow me to refer in detail to more than one other branch of industry, and even upon this my comments must be brief. The brickfields of the Black Country lie between Dudley and Stourbridge, a district which, like the nailers' haunt, is wild and bare.

The produce of the clay-pits is moulded into bricks, tiles, and pipes, of which enormous quantities are made here and sent to all parts of the country. The various establishments are called "yards," and employ a very large number of persons, the great majority of whom are very young females. The scene presented at these yards is somewhat grotesque. Queer clay-coloured beings, whose sex can hardly be distinguished by their dress or gait, paddle along with bare feet through the wet clay, reminding one of the quaint representations of Egyptian brickmaking in the days of Pharaoh. As they run from place to place, they sing snatches of coarse songs or crack obscene jokes for mutual encouragement. The hours of labour are nominally from 6 a.m. to 6 p.m. for the girls, but these hours are often exceeded. The younger girls, from eight to thirteen years old, are chiefly employed to carry bricks for the women, to fill carts, or empty kilns. As an example of the fatigue these children must undergo, I may state that a kiln containing 17,000 bricks, weighing 7¼ lb. each, was recently emptied by ten little girls in a day and a half. Each girl had consequently to catch and toss on to her neighbour in a day of usual length a weight exceeding thirty-six tons, and in doing so to make backwards and forwards, 11,333 complete half-turns of her body while raised from the ground on a sloping plank.

The foreman's account of these girls was that they were "very bold and cheeky." Even the youngest among them seemed able to appreciate the ribald jests of their elder sisters. The nature of their occupation is quite opposed to every feeling of refinement or modesty. I dare not attempt to describe the impurity of language I have too often heard among these girls, even of tender ages.

Laying aside the other part of the subject—the employment of women—I venture to think that these simple statements, in regard to the children of the district, will suffice to satisfy those who deny the need of Government interference or the necessity of some reform. And allow me to ask them, in conclusion, to consider how many girls are being led to untimely ruin, and how many boys are rising up to swell the ranks of ignorance and crime, before they quote again the oft-urged plea that Parliament has no right to pry into such matters as these.

Co-operation and the Journeymen Bakers.

We felt it our duty, in the interests of humanity and of that class for the benefit of which our efforts are more especially intended, to draw public attention upon two occasions to the melancholy condition of the journeymen bakers in London and elsewhere.* We turn now with pleasure to a more agreeable task—that of chronicling some successful attempts to inaugurate a better state of things. The tyrant's plea, necessity, has generally been the excuse offered by master bakers, and the facts we shall adduce will show whether it will avail to exonerate them from the guilt of destroying the health and shortening the life of thousands of their fellow-men. If we can prove that it is possible to bake bread by day, in healthy, cheerful buildings, and without keeping the men at work for more than twelve hours, including their meal-times—if we can prove this, and that for bread so produced a ready sale can be had, then we shall have disposed of the only ground upon which the master bakers can rest their innocence of the great crime laid to their charge.

We are prepared to prove these statements to the letter.

Some years ago an agitation was set on foot in Ireland for the purpose of improving the condition of the journeymen bakers. The movement excited a good deal of attention, and a mass of evidence was brought forward which showed that anything more deplorable in point of immorality and of physical discomfort than the state and habits of this body of operatives could hardly be imagined. Depravity, disease, and death claimed them from their apprenticeship as their appointed victims. The public were somewhat shocked by these disclosures, and there was no lack of sympathy with the sufferers; at least, of that cheap kind of sympathy which evaporates in commiserating looks and expressions of pity—"poor creatures," &c. &c. Under the pressure of public opinion, the master bakers in one or two of the provincial towns for a time adopted the principle

* See pages 217 and 241.

of day labour, but after a while they dropped off one by one, and returned to the old course; those who held out longest giving in at last for fear, as they alleged, that they would lose their customers on account of their inability to supply hot bread in time for breakfast. Public interest, meanwhile, died out, and the working bakers were silently allowed to sink back into their former state of misery. One or two master bakers, however, to their honour be it spoken, resolved to hold fast by the right, and they now remain as a protest against the needlessness and iniquity of the present system. Among those who have done so is Mr. Hughes, of Belfast, who has fifteen ovens at work, and employs numerous men in his establishment. It is now two or three years since Mr. Hughes adopted the day system, and it has proved a perfect success in his hands. We are not sufficiently well acquainted with the details of his establishment to describe his method of doing business, but we have watched with great interest, for the last month or so, the working of a day-bakery recently opened in Dublin. Our readers will hail the event with all the more satisfaction when they learn that it belongs to a Co-operative Society, and furnishes another instructive example of the benefit which this new system of industry is calculated to confer on the working man.

The central shop and bakery of the Dublin Joint-Stock Society is situated in High Street, in the heart of one of the most populous districts of Dublin, within two or three minutes' walk of the Four Courts and the Castle. Though it is only a few weeks since the company opened, they have found it necessary to establish branch shops through the city, the demand for their bread running so far in excess of what could be immediately supplied by the carts and horses provided for the purpose, and the number of customers is continually on the increase. Their bakehouse, constructed from designs by their architect, Charles Houston, Esq., is a spacious, cheerful, well-lighted and ventilated building, substantially built, neatly coloured in blue and white, with tiled floor. The bread is conveyed into the bread-room by a cart running on a tramway raised above the troughs where the dough is kneaded, and the men, therefore, are saved all the labour of carrying *themselves* as well as the bread—a matter the importance of which may be estimated from the articles on the subject of economical labour, by Professor Houghton, in the Working Man. The men come to work at five in the morning, and leave off at about the same hour in the evening. The last batches baked are carefully packed in an air-tight apartment, where they remain all night, and are taken out next morning in that wholesome and palatable condition in which a loaf that has been baked four or five hours and left in the open air will be found. The first batches baked in the morning are ready for delivery about nine o'clock, and those who wish for hot bread once a day, can have it with their tea at six or seven in the evening—a fact which many persons are finding out and taking advantage of.

The success of this experiment in day baking has been so complete and signal, that there are rumours rife in Dublin of its being the intention of some of the leading master bakers to follow the example of the Dublin Joint-Stock Society. We hope this may be the case. If so, and if the system should become general, it will be another and by no means an insignificant triumph achieved by Co-operation in the field of humanity, and will be a subject of life-long satisfaction to the few working men who set on foot the project, at one time seemingly hopeless, of a Co-operative Day-bakery. Now that the real difficulties have been surmounted, the duty of every one is clear—of the master baker to discontinue night-work; of the public to discontinue eating at breakfast hot bread, which cannot be produced except at a sacrifice of comfort, and health, and life which it is appalling to contemplate. We have now done our duty in pointing out the evil and the remedy. It rests with our readers to say whether they will remain under the guilty responsibility of being accessory to the early death of so many of their helpless fellow-citizens.

Coal Oil.—Coal oil is a better article for preserving sodium and potassium than naphtha. In coal oil sodium keeps its lustre for months and years, whilst in the purest naphtha it is dimmed in a few days.

Facts and Memoranda.

Rich silver mines, it is said, have been discovered in Hanover County, Va.

A curious type-setting match recently came off at Iowa City, Mr. A. J. Kenny, of the Iowa City *Press*, and Mr. O. B. Bell, of the Council Bluff *Nonpareil*, each setting four thousand ems solid bourgeois in two hours.

In making heavy forgings the effect of the blows of a steam hammer is found to produce a singular form of internal hollowness or unsoundness at or about the centre of the mass where it may have been previously sound.

In fourteen English towns of second-rate magnitude, 24 gallons of water a day are supplied to each inhabitant. In Manchester, 20 gallons; in Liverpool, 30 gallons; in London, 50 gallons; in New York, 300 gallons. Ancient Imperial Rome received from 300 to 340 gallons per head daily.

The alcoholic beverages, exclusive of cider, British wines, and home-brewed beer, on which we paid duty during 1862, amounted to 373,000,000 gallons, or sufficient to fill a canal 3 feet deep, 6 feet wide, and 640 miles long; that is, 40 miles in excess of the distance from Land's End to John o' Groats.

Imports of Corn.—In the year 1862, we imported 16,000,000 quarters of corn, or sufficient to build a wall 13 inches thick, 20 feet high, and 1,460 miles long; that is, the perimetre of the triangle of which the Land's End, the North Foreland, and Dunnet Head are the angular points. The flour and meal imports were 360,000 tons.

Bones.—The quantity of bones imported into the United Kingdom continues very considerable. In the first three months of this year the aggregate imports were 12,472 tons, as compared with 7,850 tons in 1865, and 14,424 tons in 1864 (corresponding periods). Liebig, the great chemist, asserted recently that all Europe was ransacked to supply England with bones.

Water, in passing from the solid to the liquid state, converts 140 degrees of sensible heat into latent; in passing from the liquid to aëriform condition, it absorbs 1,000 degrees of heat, rendering it latent. Alcohol, in evaporating, absorbs 374 degrees of heat; ether, 163 degrees; and spirit of turpentine, 138 degrees.

A useful bill, protecting immigrants, has just passed the American Congress. It establishes immigration offices in Boston, Chicago, New Orleans, San Francisco, Baltimore, and Philadelphia; provides that males unaccompanied by females shall be separated from the rest by a bulkhead; for disinfectants and the sanitary care of passengers; for limitation of the number of passengers on any ship; and for the punishment of any captain importing a convict.

The Rag Business in New York.—Mr. M'Knight, a prominent rag-dealer, has asserted that the rag business in New York city amounts to 50,000,000 dols. annually. There are 10,000 persons employed in the business, and funerals among them are said to be very rare. It was stated by Mr. Thomas Jackson, who has been in the business forty years, that although rags from pest-houses carry with them pestilence, nevertheless, if the business is well managed, with proper disinfectants, it is not necessarily dangerous.

Lucifer Matches.—The manufacture of lucifer matches has always furnished a problem the solution of which both science and philanthropy have long been seeking to discover. The lucifer match is recognised as an enemy which every man finds ready to deal at his hearth, when least expected, the most dreadful death amongst his household. M. Gaillard has just presented to the Académie a method by which all danger is obviated. The novelty consists in simply dipping the matches into sulphur after having plunged them into the phosphorus; the sulphur, being insoluble in water, prevents the phosphorus from dissolving in alimentary liquid matter, so that all danger of poison is avoided, while the more powerful friction necessary to cause combustion will be the surest guarantee against fire.

Consumption of Beverages, &c.—In the year 1865 the quantity of tea retained for home consumption in the United Kingdom, ever advancing, rose to 97,834,600 lb., averaging 3·29 lb. per head of the population, and bringing to the revenue an average contribution of 2s. 1¾d. per head; but the duty is now reduced to 6d. per lb. The consumption of coffee, which has been declining for some years, fell to 30,505,872 lb., averaging 1·02 lb. per head, and a contribution of 3d. per head to the revenue. The consumption of sugar increased, and averaged 39·89 lb. per head, and a contribution of 3s. 5¾d. per head to the revenue. Of tobacco 1·31 lb. per head, and 4s. 2d. to the revenue. Of malt 1·587 bushels per head, and 4s. 2¾d. to the revenue. The consumption of wine and spirits increased. 11,993,760 gallons of foreign and colonial wine were retained for consumption, averaging 0·40 gallon per head, and 11d. per head to the revenue. Foreign and colonial spirits 6,732,217 gallons, averaging 0·23 gallon per head, and 2s. 4d. per head to the revenue. Home-made spirits 20,711,155 gallons, averaging 0·695 gallon per head, and 6s. 11¾d. per head to the revenue. Therefore, on tea, coffee, and sugar the year's taxation amounted on an average to 5s. 10½d. per head of the population; on spirits, wine, and malt, to 14s. 5½d.; on tobacco, 4s. 2d.

Textile Manufactures of England.

BY WILLIAM ROSSITER, HISTORICAL SCHOLAR OF WORKING MEN'S COLLEGE.

V.—GENERAL VIEW OF THE MANUFACTURES.

(Continued.)

The great centre of our spinning and weaving is Manchester, with which Liverpool should always be coupled, since—though thirty miles apart—they are really but the two halves of one great whole. The population of Manchester is nearly, if not quite, half a million in number; that of Liverpool, over 300,000. Numerous other towns are worthy of special mention, but the following table will show what counties have manufactures of textile fabrics, and the peculiarities of each, together with the names of the more important manufacturing centres. The table is compiled from the facts given in Brewer's "Historical and Geographical Atlas:"—

COUNTIES.	TEXTILE MANUFACTURES.	IMPORTANT TOWNS.
ENGLAND.		
Cheshire	Cotton and silk	Stockport, Macclesfield.
Derbyshire	Cotton, hosiery, lace	Derby, Cromford
Durham	Woollen, cotton, linen	Durham.
Lancashire	Cotton (of all kinds), coarse cloths	Manchester, Stockport, Bolton.
Leicestershire	Hosiery and lace	Leicester.
Norfolk	Shawls, crapes, silk, wool	Norwich.
Nottinghamshire	Hosiery and lace	Nottingham.
Oxfordshire	Blankets	Witney.
Warwickshire	Ribbons	Coventry.
Westmoreland	Cotton and coarse woollen	Kendal.
Wiltshire	Broad cloth	Trowbridge.
Worcestershire	Carpets	Kidderminster.
Yorkshire	Woollen cloths, carpets	Leeds, Bradford, Halifax.
WALES.		
Montgomeryshire	Flannel	Newtown.

A factory is, generally speaking, a square-cornered, four-sided building, of from five to seven stories high, with very little, if any, of ornamentation about it. Each story is usually a plain room of four walls, a floor, and a ceiling, with literally no fixtures whatever. Each room is devoted to one of the several processes of spinning, weaving, &c., being, as a rule, full of the machinery adapted for that particular process, with only spare room enough for necessary walking about.

The whole of the machinery is moved by either one large, or two small engines, varying in total power, from 40 to 100 horse power. Generally a long shaft runs through the entire length of the building, with which the different machines throughout the mill are connected by bands. This machinery does the actual work of the entire series of processes, the hand labour being only necessary to keep the machinery supplied with material, to mend broken threads, take away finished work, &c. Besides thus doing the actual work of spinning or weaving, &c., the steam-engine also works, generally, a "lift" or "hoist," that is, a square wooden box or cage, in which the workpeople, managers, materials, &c., can be raised or lowered to any part of the floors of the building. The workpeople themselves are also supplied with hot water at breakfast-time, by means of a boiler heated by steam pipes from the engine pasing through it.

The number of persons employed in a mill, whether for spinning, weaving, cotton-printing, &c., is generally very considerable, varying from 300 in a small mill to 1,500 or nearly 2,000 in a large one. The wages average some 30s. for men, 12s. to 16s. for women, and 5s. to 8s. for children; the hours of work are from six in the morning till six at night, with half-an-hour allowed for breakfast and one hour for dinner. The hand-work is scarcely in any case laborious, but requires constant attention and care. The machinery possesses everything but judgment: this must be supplied by those who are looking after it.

In a spinning-mill, the only processes are those required for converting the bales of raw cotton, wool, &c., into long threads fit for weaving. These threads are called "yarn," and are of many different degrees of fineness. In a weaving-mill, the only processes are those required for making the long threads, or yarn, into fabrics of different kinds. In very many cases, however, the same mill is both a spinning and weaving mill, and

the raw material entering the building leaves it only as the finished fabric, ready for use. The capital required to set up a mill, whether for spinning or weaving, or both, is considerable. Besides the cost of the building itself, and of the engine and gearing to convey the motive power to the different rooms, there is the very heavy expense of the numerous machines used in the different processes; the number of each varying from a few up to two or three hundred, and the cost of each from a few pounds up to hundreds.

In these mills the raw material goes through very similar processes, whether it be cotton, wool, or flax. Silk is treated somewhat differently, on account of its being already in long threads.

The chief processes, speaking generally of all fabrics, are

1. Preparing the raw material for spinning.

This varies much with the material, but may be generally called cleaning and opening. Cotton is opened and dusted, wool is washed, flax is steeped and split up into finer fibres, silk is unwound from the cocoons in which it is spun.

2. Carding, or arranging the short fibres into a long "roving," or thick loose rope.

This applies only to cotton, wool, and flax. The short fibres are combed out, so as to lie all in the same direction, and by gentle pressure in drawing them between two rollers, they are made to adhere to each other sufficiently to form a continuous loose rope, called a "roving."

3. Spinning, or twisting.

By this process the rovings are twisted into a fine thread. They are thus made of sufficient strength for weaving, or for use for sewing. Each short fibre being tightly twisted with many others, a strong thread can be made of any required length.

4. Weaving.

By this the threads are made into the innumerable fabrics, known as calico, cloth, canvas, silk, linen, cambric, carpets, blankets, muslins, &c. The two sets of threads thus woven together are called—the one, the stronger of the two, running along the cloth, the *warp*; the other, less strong, running from selvage to selvage across the cloth, the *weft*.

5. Printing, dyeing, &c.

These processes are innumerable, and as different as they are many. Generally, it may be said that by means of chemical action the fabrics are made to assume different colours, these colours being generally arranged to represent ornamental figures.

Each of these processes, as well as the subordinate ones, will, in another paper, be spoken of more fully, as well as the machinery by which they are carried on.

TRADES UNIONS.

Although the workmen's unions cannot raise the rate of wages, yet they are for some other purposes a powerful institution; they have promoted free thought and free action amongst the hand-working classes, and, moreover, have taught them to respect the law, and rely upon moral means for obtaining what they believe to be right. We have now no bloodshed, no rioting, scarcely an angry word in the bitterest and most protracted strikes. Although we owe this salutary change partly to the improved education and the higher moral tone amongst the labouring class, we owe it much more to the direct and immediate influence of Trades Unions.

The great objection to workmen's unions is the secrecy with which their proceedings are conducted. Secrecy on the part of the men, and hostility on the part of the masters, are both emanations from the state of feeling which existed under the Combination Laws, when men had their pass-signs and watchwords, and masters their treadmill. Now freedom of association has become the law, men should throw off secrecy, that badge of servility and coercion. So long as the controlling influence of any branch of labour is a secret committee, it can have no open negotiation of difference, for masters know that those who offer to treat, although really principals, yet are practically only agents with authority limited to the execution of the orders issued by a superior power. Unless the wire-pullers can be addressed, it is of no use talking to the puppets.

So long as Unions act in secret, they will remain under the ban of the masters, and being so, men in good work must either refrain from joining the Union, or join the Union secretly, and so feel the humiliation of duplicity; or do, as many thrifty workmen do, join the Union and contribute to its funds, without forcing themselves upon the attention of the masters by taking a conspicuous part in managing its business. This last course leads to the worst condition of workmen's societies—that in which its affairs are left to the control either of a distant committee, or of those men of restless and erratic genius, some of whom are found in every class of society, and who, attached by a very slender thread to their regular occupations, have an ever-active desire to distinguish themselves in a more exciting occupation. Such men may gain great celebrity in other respects, but they are seldom highly esteemed as workmen. So far from its being a discredit for a good workman to be placed in a position of representative trust, it is, and ought to be, regarded by all parties as an honour conferred upon him. It ought to be proof at once of private worth and public usefulness; and then a master might be proud of having the chairman, secretary, or committee-men of the Union in his employment.—*Rupert Kettle on "Strikes and Arbitrations."*

GRASS AND FLESH.

When grass becomes flesh, as it does in the ox, a good deal of useless matter is got rid of, and the true food in the grass is stored up by the ox in one part or other of its carcass. That part which forms the edible portion of the animal, and which is generally called beef, has been sifted, so to speak, by the ox from the dross accompanying it in grass, and the true golden material—the portion really useful to man—is presented to us in the form in which we can, with least work to ourselves, make a proper use of it. What is stated here of the ox applies also to the sheep, goat, the deer, and, indeed, to all the animals on which we feed, and which, in their turn, live upon grass.

The ox, sheep, &c., aid us in preparing our flesh by taking the crude material, grass, and so treating it that they disentangle the good from the bad, and hand over to us only that which can be useful to us. We may live upon grass, or parts of grasses, such as the seeds, but it requires a greater degree of force for us to form our flesh from such food than from an animal diet, as in the latter case a part of the work has already been done for us in the stomachs of the ox and the sheep.

Living on a diet consisting in part of animal food is a saving to our digestive powers, and a saving of work implies a storing up of force. Each man in a healthy condition has a stock of force, which he can expend in manual labour at the anvil or elsewhere, or in thinking, writing, or speaking. In either case the force so expended may be the direct means of procuring bread for himself or his household.

To *think* and to *work* are, in popular language, so separated from each other, that at first sight they appear quite different in all their relations; but the thinking or mental powers, and the bodily or physical—in other words, the thought and the arm—draw on the same bank or stock-in-trade. They are two partners in the same concern, and the more there is squandered on the one, the less there is left for the other. And thus the smaller the force which is expended in the digestion of food—and of all work, stomach work is the hardest—then the more force or power there remains for the exercise of thought.—*Macadam's Chemistry of Common Things.*

WASTE OF COAL.

There are several systems of getting coal, which, for want of space, we are unable to describe. A comparison of these with each other would clearly show that, while loss takes place in all, they differ considerably as to the degree of waste. In the "long wall" system the whole of a seam is extracted at one getting, no ribs and pillars are left, and the roof, with all the superincumbent strata, falls gradually as the work of extraction proceeds, filling up the space previously occupied by the coal. Theoretically and practically this system is the best; but in some collieries, where the roof is bad, it is absolutely necessary to leave a considerable layer of coal for the purpose of forming a secure roof, and the whole of that coal is irrecoverably lost. In the "pillar and stall" system the coal is extracted in two gettings. In the first, large ribs and pillars of coal are left to prop up the roof of the pit, and these are taken out at the second getting; but in this second process there is always much loss, owing to the crushing of the ribs and pillars by the enormous weight upon them, and the consequent production of a large quantity of fine, and, if the coal be non-caking, worthless slack. Of all the coal-seams of Great Britain, the greatest waste has occurred in that known as the "ten-yard" or "thick-coal" of South Staffordshire. The seam ranges in thickness from eight to ten yards, and is composed of a series of distinct beds, varying much in quality. It is now on the eve of exhaustion. With very few exceptions, it has been gotten on the "pillar and stall system," huge pillars about ten or twelve feet square and enormous ribs, being left in the first working. The residual coal was imperfectly extracted in a second working; and some of the old pits have been thus rifled over several times in succession. This coal is wholly non-caking, and it may be confidently asserted that millions of tons of this slack now lie buried in the worked-out collieries of South Staffordshire, it is to be feared without hope of resurrection; yet every ton of that slack has stored up in it as much heat-giving force as the same weight of solid coal! The fine slack of this coal is particularly liable to spontaneous ignition, which has often occurred in the first getting, and very frequently in the second. It is the curse of the "thick coal," and has occasioned the destruction of a large amount of property and great pecuniary loss. In some cases the "thick coal" has been extracted on the "long wall" system in two, or even three gettings, and with a much larger yield per acre; but as this seam is in many localities greatly disturbed by faults, it is probable that the "long wall" system would not have been generally applicable, for reasons that will be immediately appreciated by colliery engineers, though not by the general reader.

It is a fact known to every well-informed colliery engineer in the kingdom that the working of this fine coal-seam, far exceeding in thickness any other in Great Britain, has, for the most part, been entrusted to unskilful and often unscrupulous persons. Indeed, at one time even the bare mention of the term colliery engineering in South Staffordshire was regarded as a joke, and excited sceptical laughter; but it was no joke, either to proprietors, lessees, or the nation. It is scarcely possible to over-estimate the destruction of coal which formerly resulted from a combination of ignorance and roguery. All this is perfectly notorious both in South Staffordshire and elsewhere. It is not pretended that there have not always been honourable exceptions to this censure, or that in this county colliery engineers do not now exist as well instructed in their art and as upright as can be found in any other part of the kingdom. There are, happily, many such, and they are well known and appreciated.

The specific gravity of the South Staffordshire coal is stated to be about 1·3, so that a cubic yard should weigh 2,190·24 lb., or nearly the statute ton of 2,240 lb. Hence, inclusive of thin layers, termed partings, an acre of the "thick," or "ten-yard" coal should contain somewhat less than 48,400 tons, and an acre of the same coal eight yards in thickness somewhat less than 38,720, say 38,000 tons. Now, it is certain that, on the average, *at least* one-third, or 12,000 tons per acre, have been irremediably lost from the mode of getting as previously described. But, as usual, where God has been most bountiful, man has been most prodigal. Imagine that enormous store of force, which, as we have seen, it may have required millions of years to accumulate, not only lost, but in great measure needlessly and wickedly wasted. Warning, alas! comes too late, for the mischief is done, and the nation has been robbed of what never can be restored.—*Quarterly Review.*

Things Talked About.

Mr. Clay's Educational Franchise Bill, which has been so well discussed in our Correspondence columns, has been very warmly debated in the House of Commons, and its fate is as yet undecided. A division on the question of the second reading was evaded on Wednesday evening by the familiar process of "talking against time." All our readers are perhaps not aware that in the House on Wednesdays all discussions are adjourned at a quarter to six o'clock, so that if either the advocates or opponents of a measure feel themselves too weak in the state of the House to hazard a division, they have only to put up some of their long-winded speakers, who keep the game alive till the hands of the clock point to the fatal fifteen minutes to six; then a week must elapse before the subject can again come on, and as the business of the succeeding Wednesday is already arranged, most possibly the measure is indefinitely shelved. Such may be the fate of the Bill which proposes that every man of mature age, and unconvicted of crime, shall, if he can read, write, and cipher, be entitled to the franchise. It was singular to hear the very same politicians who, a few weeks since, were horrified at the idea of a few thousands of working men being admitted to the franchise, warmly supporting a measure which proposes the nearest approach to universal suffrage ever broached in the British Parliament.

But it was more amusing still to hear Mr. Gladstone, who, like Michael Cassio, is "a great arithmetician," tell the House that he did not believe thirty members in it could work a sum in the division of money. If the Chancellor of the Exchequer is right in his supposition, it speaks ill for the intelligence with which the estimates are discussed. And, perhaps, if Mr. Clay's measure should be carried, it would be as well if the candidates, as well as the constituencies, were subjected to an interview with the arithmetical examiners. Mr. Gladstone proposed a test question: "He would like to know how many members of that House would be able, say to divide £1,330 17s. 6d. by £2 13s. 8d." "It is not to be done; it's impossible," called out Lord Robert Montagu, the member for Huntingdonshire, M.A. of Trinity College, Cambridge, and author of a work on naval architecture. "But it can be done," replied the Chancellor, and he adroitly clenched the argument by the instance afforded:—"One illustration is worth a thousand arguments. Here is one of the financial authorities of the House telling us that such a thing cannot be done." Clearly, Lord Robert would not pass Mr. Clay's examination, if Mr. Gladstone's poser were propounded.

And a poser it is at first; but examined carefully, the problem is simple enough, and any engineer familiar

with the sliding-rule would not hesitate over it a moment if differently stated. The question is simply, "How many sums of £2 13s. 8d. are there in £1,330 17s. 6d.?" Simple reduction and division will give the answer, and there are shorter, if more complex, methods of arriving at the same result. The answer is $495\frac{23}{33}$, or £2 12s. 6d. over.

It is anything but satisfactory to know that just at this time, when there are political and commercial convulsions at home and abroad, when funds and markets are falling, and no man can say what another week may bring forth to affect trade and manufactures, that the almost absorbing topic connected with the condition of the working man is that strikes are everywhere prevalent, and that there is—at present, at least—very little chance of the objects for which the men are striving being obtained. The Sheffield file-grinders, it would seem, have by their determined opposition to the introduction of machinery really precipitated the evil they have been most desirous to avoid. Messrs. Chubb and Son, the lockmakers of St. Paul's Churchyard, have published an extract of a letter they have received from one of the first firms in the file trade. The writer says:—"We have already succeeded in introducing a machine that will efficiently grind files, and are now at work building other machines for forging and cutting them, so that in a short time we hope to be in a position to fill orders better than ever. In the meantime the workmen are making a national subscription to keep them out, but in the end they will find that it was a bad day for them when they left off work." From Glasgow to Greenock, on the Clyde, the principal shipbuilders and engineers have decided on a lock-out. At Liverpool and the Port of London sailors are on the strike; and we regret to add that, on the former part, some cases of intimidation have occurred. The Mercantile Marine Stokers' United Friendly Society asserts that its rules against intimidation are very stringent, and provide that any member convicted of intimidating a non-society man shall be fined 10s. for a first offence and 20s. for a second, while, should he be convicted of a third infringement of these regulations, he will be expelled, and forfeit all claims on the society. This is as it should be. Violence is the very worst argument, and will inevitably alienate popular support from what may be in itself a most meritorious cause.

In London, a "London Seamen's Protective Society" has been formed, and many members have been enrolled. For voyages to Australia, New Zealand, and elsewhere round the Cape of Good Hope, an advance of 10s. a month is claimed; and, in some cases, to avoid detention of the vessels, the advance has been given. The following scale is demanded by the Protective Society:—"Steamships, £5 per month for the Baltic and North America; £4 per month for the Mediterranean and ports southward of New Orleans; 5s. per day for daily wages, and 8d. per hour overtime. Sailing ships, £3 10s. per month round either of the capes; £4 10s. per month, with or without advance, for all western voyages; £3 10s. per month for the West Indies, Mediterranean, and south of the Line; 5s. per day for daily wages, and 8d. per hour overtime." In the course of the discussion of the subject, it was mentioned that the boarding-house keepers would assist the men while they were holding out for the advance, if any should be turned out of the Sailors' Home. May we venture to suggest that the keepers of sailors' boarding-houses, as an antidote to whom the Sailors' Home was established, are not probably the best advisers the men can have?

A case of some interest to members of provident societies has been heard at the Mansion House. Mr. Edward Sayer, the secretary to the benefit society called the "Brewers', Chester and Galley Quays' Provident Society," attended before Mr. Alderman Besley, to show cause why one of the members, named James Foley, who had been expelled from the society, should not be reinstated as a member. The complainant was a labourer at Scovell's Wharf, and it appeared that on the 4th of April he had the misfortune, while employed at his avocation, to break his collar-bone, and he applied to the society for the usual allowance. Accordingly, he was paid £1 a week as a first-class member, and this sum was continued until the 7th of May, when it was stopped, and a meeting of the committee of the society was convened, and he was expelled, on the ground that, in contravention of the 19th rule of the association, he had been at work while receiving the allowance from the society. The committee of the society, it appeared, had acted upon hearsay, and had not allowed the complainant to be present when the matter was discussed. Had he been questioned then, he would have been able to prove, as he did before the alderman, that the statement as to his being at work was quite unfounded. An order was made for the reinstatement, and that the amount to which he was entitled should be paid to him from the period at which the allowance had been stopped. Precipitancy is always an evil; and the utmost fairness and consideration should be shown in such cases where, by undue haste, or refusal to listen to explanations, great wrong may be done to industrious and provident men.

Art unions, by which many of the upper and middle classes are able to obtain possession of choice specimens of art for the adornment of their homes, have been hitherto out of reach of the working classes, who would gladly have a good picture or a statuette if it could be brought within their means. An International Art Union has been started, which offers prizes varying from 5s. to £100 in value for 1s. subscription. Lord Teynham is at the head of the directorate.

A gold medal has been awarded by the French Minister of Public Works to a Liancourt firm for the construction of a steam coach to run on common roads. This steam coach, we are told, lately descended the hill from Laon to the railway terminus at the rate of five miles an hour, and afterwards ascended the same hill in eight minutes with a weight of five tons. The trial was repeated with so much success that it is now ascertained the steam-engine can draw a weight of thirty tons on an ordinary road at the rate of from three to four miles an hour.

We must, it seems, keep a sharp look-out for the security of our pleasure-grounds. A portion of Greenwich Park is now threatened by the authorities of the Admiralty, who propose to let it on building leases. It is not a large plot, certainly, but too large to be spared from a public park. Besides, a principle is involved; and we are therefore glad that Mr. Alderman Salomons has taken up the matter, and that strong representations will be made to the Admiralty on the subject.

Co-operative Intelligence.

CHESTER-LE-STREET.—At the fourteenth quarterly meeting of the Chester-le-Street Co-operative Society, the secretary, Mr. James Wilkinson, read the report, which showed the receipts to be £2,628 0s. 8½d., being an increase over last quarter of £499 19s. 10d., which enabled the committee, after allowing five per cent. on all paid-up shares, to reduce the fixed stock £20 8s. 4½d., and to declare a dividend of 2s. to the pound on members' purchases. Fifty-eight new members have been enrolled during the quarter, and sixteen have withdrawn, showing an increase of forty-two, which makes a total now on the books of 313.

DUNSTAN CO-OPERATIVE STORE.—The fifth annual *soirée* of this store was held on Whit-Monday, when the secretary, Mr. William Marshall, read the annual report, which showed the society was in a very flourishing state. The income for the last year was £6,023 0s. 1d., being an increase of £428 16s. 9d. on the previous year. There has been paid during the last year £38 7s. 10d. for reduction of fixed stock, £35 11s. interest on members' capital, and £372 4s. divided on members' purchases, besides £20 4s. 5d. on non-members' purchases. Since the society commenced in 1860 there has been taken £21,277 1s. 10d., leaving a clear profit of £1,806.

General Information.

CLUBS AND INSTITUTES.

MARKET DRAYTON.—A public meeting was held in this little town on the 29th ult., to call attention to the Working Men's Club recently formed there. The chair was taken by Dr. Saxton, and the meeting was addressed by the Rev. Henry Solly, of London. Harcourt Griffin, Esq., of Pell Wall—a beautiful estate in the neighbourhood; his brother, of the Royal Artillery; A. W. Radford Norcop, Esq., of Bettonhall; and Messrs. Onions, Wilkinson, and Rodenhurst (proprietor of a large iron foundry) were on the platform, and, with Dr. Saxton, take a warm interest in the movement. Mr. Horner, solicitor, gave an interesting account of the Duck Lane Club, Westminster. Mr. W. Talbot, the secretary, a working man, moved the usual votes of thanks, which were passed with acclamation.

NEWPORT, SALOP, WORKING MEN'S CLUB.—A large and crowded meeting was held in the Town Hall on Wednesday evening, the Rector, the Rev. D. Mountfield, in the chair. Various songs and recitations were given with excellent effect in the course of the evening, and the Rev. Henry Solly gave a description of the advantages these clubs are conferring on working men and their homes in various parts of the country. A considerable portion of the audience consisted of the fair sex, who seemed to enter thoroughly into the spirit of Mr. Solly's statements; and a large number of working men were present, who, it was said, had never attended any previous meeting, either for the Club or for the Penny Readings. The main secret of the success of these present attempts was, that the town was divided into districts, and a number of gentlemen went round to the homes of the working men, offering free tickets of admission to those who liked to take them. Nearly 700 people were present. The Rev. Henry de Bunsen, Rector of Lilleshall, C. C. Walker, Esq., and J. Bodenham, Esq., Manager of the Bank, were on the platform; and on the following morning several clergymen and large employers of labour assembled at Mr. Bodenham's house for a conference with Mr. Solly on the subject of Working Men's Clubs, the chair being occupied by the Rev. Henry de Bunsen.

Correspondence.

**** We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* WORKING MAN, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*
We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

WHAT TRADES UNIONS MIGHT BE.

To the Editor of the WORKING MAN.

SIR,—The WORKING MAN contains (19th May) some communications of much interest, which deserve to be considered together, for the lessons they convey as to what Trades Unions, properly managed, keeping up a good understanding with employers, ought to secure for the good of their members.

Grouping the subjects together, we take first those relating to workmen's dwellings: "Working Men's Building Societies;" "As the Home, so the People;" and "The Workman's City"—the last a most interesting account of what the Brothers Japy, of Beaucourt, Haut-Rhin, have done for the comfort of their working people's dwellings. The high value of land here may prevent anything like the space there mentioned from being given to each workman's home in England; still there is much in the general features of the plan, and in some details of comfort, that might well be copied, in its enviable contrast with too many of the hovels and wretched cottages allotted to our labouring classes. In many cases it is absolutely needful that the homes should be provided by the masters, to combine lodging for large numbers near their work with the needful freedom of removal when the men change employment. Here the Trades Union should carefully watch that the houses so provided are healthy and comfortable, and the rents moderate. This is the proper business of the Union, and cannot so well be cared for by each individual acting for himself. The masters would be forced to attend to the reasonable demands of a body representing all their workmen who claimed good air and water, with home comforts; and would find it their interest to plan buildings suited to the wants of their men, when they saw that the lodging was as well cared for by the Trades Union as the wages. In cases where it answers best for workmen to own their own dwellings, their Trades Union should either be a building society on the best system, or be so connected with such a society as to give the fullest advice and help to the members in all details, enabling them to have healthy, comfortable homes for far less cost than they now too often pay for mere fever dens, where it is all but impossible to rear a healthy family.

2. As to skill and machinery, the articles on the "Origin of Trade Guilds" and the "Trades Unions of Sheffield," as well as that just noticed on the works of Messrs. Japy, are well worth attention as to these matters. Trades Unions ought to take the place of the Guilds of former times, having periodical exhibitions, and giving prizes to keep up the high character of English work, for this is the only certain ground for the permanent security of high wages. The superiority of English work gives our workmen the best kind of monopoly—that founded on high skill and thorough completeness of all they turn out in every department. As long as no master can employ foreign hands to any extent without the risk of some inferiority or shortcoming in their work, so long are our trades and manufactures sure to be permanently prosperous, far ahead of all competition. The fund for payment of wages depends on this prosperity. All that Trades Unions can do is to help the workmen to secure his fair share of this profit. They cannot create or increase the trade profit which nourishes this wages fund, except as above pointed out, by keeping up the character of English work above all rivalry. The account of the hollow ware manufactory of the Messrs. Japy deserves their careful thought, as proving the sheer folly of resisting the introduction of machinery or of any improvement, from a shortsighted, mistaken notion of thereby protecting their interests. All the effect of such folly is sooner or later to enrich foreign lands at the expense of our own country, by creating establishments like those of Messrs. Japy to compete with and under-sell us. In this respect the Americans are far more enlightened. They know the value of machinery and new inventions, as securing that manufacturing prosperity which pays the highest wages. Therefore, until our English Trades Unions are equally sensible and well-informed, we shall always compete with them at a great disadvantage in many respects.

3. What is now taken to be almost the sole function of the Union—the regulation of work and wages—is (though they have, as we have noticed, other most important duties) nevertheless their main aim and business. For this they are called into action and kept in existence. If they fail here, they are almost helpless for good in any other way; and on the other hand, when their wise conduct keeps their members prosperous and contented, their power, warily exercised, is of vast extent. The article "Out of Work" has a strain of truth that must come home to the feelings of all who know anything of the real life and fortunes of working men; and the several notices relating to emigration suggest many of the most important duties of Unions hitherto too frequently neglected. Much has been and is daily written about supply and demand applied to labour by half-informed people, either mistaking the indisputable truth and facts of the case, or fancying they refute them when exposing absurdities, in reality wholly of their own creation, from drawing extreme and false conclusions from true premises. In all these instances, the fallacy once pointed out is too glaring to bear a moment's reflection. Unions are daily growing wiser in this matter, often from bitter experience, but they have yet too generally much to learn. The great point is to get fast hold of true principles, and follow them fearlessly, without pushing them beyond the safe ground which alone

can give sure foundation. It is childish to deny the manifest truth that rates of wages and full work depend mainly on the proportion between the numbers competing for employment. The Trades Unions are right in keeping this steadily in view. Their most dangerous error lies in mistaking the extent to which they have power to regulate this supply and demand, and the means they employ for the purpose. No safe action can be taken at any point that is not based on some knowledge of the real state of the trade, and some sagacity in computing its present and future prosperity, on which all security of work and wages must depend. It is true, as Mr. Kettle remarks, in the extract quoted by you (26th May), that wholesale indiscriminate emigration, rashly undertaken, is almost always disastrous. But this is a widely different matter from systematic proceedings founded on full, accurate information, and carefully kept in proper bounds by an active and intelligent Trades Union. If these Unions discharged their functions properly, your pages could not be taken up with discussions as to differences of net earnings, taking rates of wages and cost of living, between Canada and the States. If proper care was taken to procure trustworthy letters, brought down to the latest moment, the purchasing power of States notes compared with Canada coin, and all relating to the condition of workmen in both countries, would be known and computed to a farthing. And just as accurate information would be regularly procured as to work in every quarter of our own country, our colonies, and, as far as possible, for the Continent. This is the sound basis for regulating the supply and demand of labour to prevent local differences to the injury of the workman. Thus the managers of Unions would know beforehand all the chances masters have at any time of getting work done on much lower terms than the current wages. To this point the rate of payment will surely tend, sooner or later, like a scale finding its balance after many vibrations, and on the fixture of this point depends the certain holding of any advantage workmen may for a time have secured. Thus would be avoided the mistake the ironworkers made, who have just returned disappointed from the United States; and the vast savings from preventing ill-advised quarrels with their employers would enable Trades Unions to found and keep up such flourishing benefit societies as that of the Amalgamated Engineers, noticed by you (26th May). Perhaps, also, prosperous Unions could eventually extend their support to cases of temporary loss of work by members who had contributed to their funds for a given period, or make, under fixed regulations, advances to help emigrants in special cases. A Trades Union, opulent and wise enough thus to support its members, would never be driven to waste money in strikes. As they would never be so foolish as to demand what is wholly unreasonable, they would soon find the masters fully alive to the necessity of avoiding collision with them by every concession which the state of trade would allow.

We are well aware that this sketch of something like a perfect Trades Union is, in many respects, very far in advance of anything existing at present. Let all members, however, steadily keep in view these benefits which a good Union ought to secure for them. If the next twenty years see as great advance as the last twenty have made, most, if not all, of these fruits of wisdom and moderation would be tasted by English associated workmen, to a degree unknown in any other land, or at any time, past or present, of which we have any record. C.

31st May, 1866.

REMINISCENCES OF PRINTING ABROAD.

To the Editor of the Working Man.

Sir,—Please to be informed by one of the most earnest, if one of the humblest, of the supporters and recommenders of your valuable journal, how much he has been pleased with most of the articles which have recently appeared therein, but more especially with that in No. 20, printed on page 314, headed "The Language of the Workshop."

What its well-informed writer observes—no doubt truly—regarding the foreign origin of the names designating the various tools employed by working goldsmiths among English-speaking populations, my own experience bids me say is yet more applicable to the technical terminology of my own profession—namely, typography; for I shall scarcely assume too much in declaring that a majority of the names for most of the tools, implements, &c., used by operative printers of universal Saxondom, within and beyond seas, are purely French.

This fact was agreeably, because conveniently, made apparent to me upon my obtaining a situation as a working printer, soon after my arrival in Paris, at the establishment of the Didots—a family of typographers of European fame. And scarcely had I crossed the threshold when, on being welcomed by the *doyen** (dean) *de la chapelle*, an intimation was made that a "bevenue" (*bien-venu*) is usually expected from every in-coming stranger! This first mention of our household word, a typographic "chapel," in a French office did, I must own, rather puzzle me; for had I not (as all or most English printers are) been persuaded to believe that their predecessors, in times remote, adopted said term to commemorate the circumstance that Caxton began his labours as a printer in a Westmonarensian disused chapel?† On proceeding to work, I soon found, as already intimated, that most of the tools and appliances I handled, or saw others around me use, had (as I thought in my simplicity) *English* names! the very reverse being the case. In proof of this assertion I herewith append a score or two names of tools, &c., set down at random from experiences first made some forty years ago:—

English.	French.	Uses, etc.
1. Balls (pair of)	*Balles (les)*	For inking types.
2. Bourgeois	*Bourgeoise*	Kind of types.
3. Brevier	*Breviaire*	Ditto.
4. Canon	*Canon*	Ditto.
5. Case	*Casse*	Type drawers, with 154 cells.
6. Chapel (the)	*Chapelle (la)*	Hands in an office (collectively).
7. Chase	*Chassis*	Iron frame for binding type.
8. Composition	*Composition*	Type set up.
9. Compositor	*Compositeur*	Type-setter.
10. Corrections	*Corrections (les)*	Emendations of errors; alterations.
11. Double (a)	*Doublon*	Faulty repetition of words.
12. Distribute (to)	*Distribuer*	To decompose type.
13. Distribution	*Distribution*	Type for decomposition.
14. Folios (the)	*Folios (les)*	"Heads;" running numbers of pages.
15. Forme (a)	*Forme*	Set-up type, inclosed in a chase.
16. Fount* (a)	*Fonte*	An assorted supply of type.
17. Frisket	*Frisquette*	Light frame auxiliary to the tympan, *which see.*
18. Galley	*Galée*	Kind of type-holder.
19. Impose (to)	*Imposer*	To put pages of type in proper place.
20. Imposition	*Imposition*	The same, when done.
21. Impression	*Impression*	Printed page, &c.; pile of printed sheets.
22. Italic	*Italique*	Italic character.
23. Justify (to)	*Justifier*	To firmly fix lines of proper length.
24. Justification	*Justification*	The same, when rightly done.
25. Mackle (to)	*Maculer*	To print slurringly.
26. Mackled (work)	*Maculature*	Soiled press-work.
27. Mallet	*Maillet*	Wooden hammer for locking and unlocking forms.
28. Matrix	*Matrice*	Letter-founders' die.
29. Minion	*Mignonne*	A kind of type.
30. Nonpareil	*Nonpareille*	Ditto.
31. Octavo	*Octavo* (in 8)	Printed sheet of 16 pages; volume made up of such.
32. Pagination	*Pagination*	Sequence of heads or folios.
33. Paragon	*Parangon*	Kind of large type.
34. Pie	*Pâte*	Mass of type in a chaotic state. [*Pâte* is French for dough, and *pâté* is a pie: the former word best characterises the amorphous nature of the thing.]
35. Press (printing)	*Presse (la)*	
36. Proof	*Epreuve*	Impression of a page, &c., for correction.
37. Quadrat	*Cadrat*	Type-metal blocks for filling up short lines.
38. Quarto	*Quarto* (in 4)	Sheets of 8 pages each; volume composed of such.
39. Quoin	*Quoin*	Small wedge of wood used for locking up a forme.
40. Reader (corrector of proof)	*Correcteur*	
41. Register	*Registre*	Exact backing of pages when printed.
42. Reglet	*Reglet*	Kind of graduated lath.
43. Retiration	*Retiration*	Counterpart form of a sheet.
44. Roman	*Romain*	Ordinary printed characters.
45. Signatures	*Signatures (les)*	Letters or figures appended to pages as indicators to folders.
46. Sorts	*Sortes (les)*	Parts of a *fonte*, more especially types of a peculiar kind.
47. Spaces	*Espaces (les)*	Short-shanked types for separating words.
48. Tympan	*Tympan*	A frame used in press and machine printing for keeping a sheet in its place.

Here I pause, Mr. Editor, in the prosecution of the task I prescribed to myself, as fearing that I have already overpassed such limits of space as you can afford to give in the present case. Should what is now sent he "received," perhaps you may not set me down for intrusive if I present for your indulgent consideration a second communication, supplementary to the foregoing notitiæ, contrasting British and French typography, especially in so far as the interests of its operatives in London and Paris are concerned.—Meantime I subscribe myself, sir, yours obediently,

Typographus Sexagenarius.

Working Man's Club, Peckham, May, 1866.

* This time-honoured functionary is called the "father of the chapel" in our printing-houses.

† "Stowe says that Caxton first exercised the art in an old chapel near the entrance of Westminster Abbey; but a very curious placard, a copy of which, in Caxton's largest type, is now at Oxford, in the late Mr. Douce's library, shows that he printed in the Almonry."—*C. Knight, Nat. Cycl.* As the father of British typography procured his presses, types, &c., in Paris, and engaged French artisans to turn them to account, it necessarily followed that all the technical terms employed by them would be adopted for use by the young Englishmen whom they trained for the continued exercise of the new art.

* *Fondre* (Fr.) meaning *to cast*, and that which is *fondu* being *une fonte*, our typefounder's term, "fount," having no proper reference to *fons* (Lat.), is evidently a misnomer.

TO CORRESPONDENTS.

A Factory Operative.—"Every manufacturer within a month of commencing business is required to send notice to the Factory Inspectors, with information as to the nature of the work he intends to carry on, the nature and extent of the moving power, the name of the firm, &c."—7 and 8 Vic., c. 15. "The hours of work must be regulated by a public clock, or a clock on the premises exposed to public view."—7 Vic., c. 15. "No children under eight must be employed, and no person under eighteen can be employed until his or her name has been registered in a book for the purpose, in form provided by the Act, and to be open to the Inspectors."—7 Vic., c. 15. "Every person under sixteen must have a surgeon's certificate as to health and capacity for labour. The surgeon must be appointed by the Inspectors, who may determine the fees to be paid by the employers."—3 and 4 Wm. IV., c. 103, and 7 Vic., c. 15. "No women or person under eighteen must be employed before six in the morning, or after six in the evening, except six winter months, when the hours may be from seven to seven, of which a month's notice must be given to the Inspector."—16 and 17 Vic., c. 104. "No woman or person under eighteen must work after two on Saturdays."—13 and 14 Vic., c. 54, and 16 and 17 Vic., c. 104. "No child under thirteen must work more than half-days, or alternate days, and on Monday, or every other day every week, must produce certificate of attendance at school on the days or half-days when not at work, and the master must pay for schooling such sum as the Inspector may require, not above 2d. per week, but this may be stopped from the child's wages, if it does not exceed one-twelfth part of such wages. Attendance at school must be between the hours of eight in the morning and six in the evening."—7 Vic., c. 15. "No child, young person, or woman must remain during meal hours in any room where any manufacturing process is carried on."—3 and 4 Wm. IV., c. 103. 7 Vic., c. 15. 13 and 14 Vic., c. 54.

W. L.—Apply to the Emigration Commissioners, Park Street, Westminster.

A Reader.—According to Mr. Smiles, it was on the occasion of the trial of "Boville v. Moore," that Sir John Copley (afterwards Lord Lyndhurst), who was retained in the interest of Mr. Heathcoat, learnt to work the bobbin-net machine, in order that he might master the details of the invention. On reading over his brief, he confessed that he did not clearly understand the merits of the case; but, as it seemed to him to be one of great importance, he offered to go down into the country forthwith, and set himself to work the machine until he thoroughly understood it, "and then," said he, "I will defend you to the best of my ability." He accordingly put himself into that very night's mail, and went down to Nottingham, where he worked at the machine, making a piece of bobbin-net very deftly, until he thoroughly understood the principle as well as the details of the invention. When the case came before the court, the learned serjeant was enabled to work the model on the table with such ease and skill, and to explain the action of the machine with such felicitous clearness, as to astonish alike judge, jury, and spectators; and the thorough conscientiousness and mastery with which he handled the whole case no doubt exercised considerable influence on the decision of the court.

Mechanic.—Original contributions, if accepted, are of course paid for. We shall be glad to see the articles mentioned by you.

O. M. N.—We could scarcely advise you, under the circumstances mentioned, to emigrate, especially when those in your trade are here obtaining such good wages. Employment is more certain in this country.

Work-a-Day.—No; the tramp system is gradually dying out.

J. Palmer.—Your letter has been forwarded to the writer of the article.

J. Johnson.—The Metropolitan, and London, Chatham, and Dover Railways, run Workmen's Trains. The other questions shall be answered in a subsequent number.

Charles Shore.—Thanks for your letter. We wish that all working men would write in the same thoughtful and aspiring strain.

E. G.—There are plenty of cheap works on the subjects mentioned by you.

"WORKING MAN" LIFEBOAT.

(*2nd List of Subscriptions.*)

In accordance with the promise contained in our last number, we beg to announce that all subscriptions above 20s. to the Working Man Lifeboat Fund will be acknowledged when the subscription list has closed.

No subscriptions will be received later than August 1st.

The Silver Medal so kindly offered by the Committee of the Metropolitan and Provincial Working Classes' Industrial Exhibition will be given to the collector of the largest sum.

The Working Man Lifeboat will be exhibited at the forthcoming Metropolitan and Provincial Working Classes' Industrial Exhibition, at the Agricultural Hall, Islington.

NOTICE.—The readers of the "Working Man" are solicited to bring the following announcement under the notice of any of their friends whom they may think will be interested.

Metropolitan and Provincial

WORKING CLASSES' EXHIBITION and INDUSTRIAL FESTIVAL, to be held at the AGRICULTURAL HALL, London, and opened on SEPTEMBER 3rd, 1866.

TO EXHIBITORS.

Contributions of Skilled Workmanship, or Amateur Productions, will be accepted from all parts of London, the Provinces, Scotland, Ireland, and the Colonies. For the benefit of Provincial Exhibitors, the Railway Companies have liberally offered to return unsold goods free, so that the expense of carriage will be but half the usual charge. Application for space to be made at once.

SPECIAL PRIZES.

The Council of the above Exhibition have much pleasure in announcing that, in addition to the MEDAL OF MERIT, designed for the occasion by J. S. and A. B. WYON, Esqs., the following SPECIAL PRIZES have been liberally offered by the gentlemen named, for the production of Articles to be Exhibited at the Agricultural Hall in September next, namely—

£15 0 0 in Money, or Silver Cup, for the MOST USEFUL INVENTION. Open to all Classes. The Gift of the Directors of the Agricultural Hall Company.

£10 0 0 in Money, or Silver Cup, for the best PAINTING IN OIL The Gift of the Directors of the Agricultural Hall Company.

£5 0 0 in Money, or Silver Cup, for the second best OIL PAINTING. The Gift of C. COMFORT, Esq.

£5 0 0 in Money, for the best WATER-COLOUR DRAWING. The Gift of J. HARRIS, Esq.

£3 3 0 for the best GOLD BROOCH and EAR-RINGS, of Original Design, which can be sold for £10. (Sale for that sum to be permitted if required.)

£2 2 0 for the best pattern, Birmingham make, GILT BRACELET, BROOCH, and EAR-RINGS, which can be sold for £3 3s. (Sale for that sum to be permitted if required.)

£2 2 0 for the best Specimen of WHITBY JET JEWELLERY.

£2 2 0 in Money, for the best WORKING MODEL of a STEAM-ENGINE. The Gift of W. J. W.

£2 10 0 for the best ARTICLE OF UTILITY, made by an Amateur. The Gift of R. MURRAY, Esq.

£2 2 0 and a Silver Medal, the Gift of R. MURRAY, Esq., for the best WORKING MODEL of a MILL to grind Stale Crusts into Flour.

£2 2 0 for the best PEN-AND-INK DRAWING. The Gift of — STRAKER, Esq.

£2 2 0 for the best Original Contrivance that may be suggested for improving the Fittings of WORKMEN'S DWELLINGS.

£2 2 0 for the best Specimen of SHEFFIELD CUTLERY. The Gift of T. RUDKIN, Esq.

£2 2 0 for the best Pair of LADY'S BOOTS. The entire work to be done by Exhibiter.

£2 2 0 for the best Specimen of INLAYING IN WOOD. The Gift of C. A.

£2 2 0 for the best Specimen of WOOD CARVING. The Gift of J. S. and A. B. WYON.

£2 2 0 for the best Specimen of CABINET WORK, made by an Apprentice who has served not more than four years to his trade. The Gift of Mr. I. HAYNES.

£2 2 0 and a Silver Medal for the best Specimen of ORNAMENTAL TYPOGRAPHY, consisting of a Quotation from Shakespeare, displayed and Printed in Colours, to occupy a royal 8vo page.

In addition to the above, the

EXHIBITION SILVER MEDAL

will be awarded to the Exhibitors of the best Specimens of

Household Furniture.	Stained Glass.
Hammered Iron-work.	Artificial Flowers, from Nature.
Watch-case Engraving.	Working Model of a Steam Vessel.
Engraving on Glass.	Statuette, in Plaster, or other Material.
Coventry Ribbons.	
Design for Paper Hangings.	
Embossing in Metal or Electro-Plate.	

☞ *Medals will also be awarded for other Articles which may be deemed worthy of especial distinction.*

All objects must be the work of the Exhibitor. In cases where Articles are the property of Employers, the name of the firm permitting their exhibition will be given in the Catalogue.

FORMS OF APPLICATION FOR SPACE may be obtained by sending a stamped and directed envelope to the Secretary, Mr. W. J. WATTS, 7, Birchmore Terrace, Cardington Street, Hampstead Road, London, N.W., or by application to any of the Honorary Agents. To be returned, filled up, on or before June 30.

Sixpence per dozen.

Open on Monday and Thursday Evenings from Five till Eight, and on Wednesday and Saturday Evenings from Seven till Nine. Free letters are available for necessitous applicants. THOMAS ROBINSON, *Hon. Sec.* [9

The Original Chlorodyne,

Invented by R. FREEMAN, Pharmaceutist, is allowed to be one of the greatest discoveries of the present century. It immediately relieves and cures Coughs, Colds, Consumption, Influenza, Bronchitis, Asthma, Whooping Cough, Cramp, Spasms, Gout, Diarrhœa, Dysentery, &c.

EARL RUSSELL communicated to the Royal College of Physicians and to Mr. Freeman that he had received information from Manilla that the only remedy of any use in Cholera was Chlorodyne.—*Lancet*, Dec. 31st, 1864. See *Times*, Nov. 14th, 1865.

Freeman's Original Chlorodyne.

—The *Medical Times*, Jan. 13th, 1866, states—"It has an immense sale amongst the public, and is prescribed by scores of orthodox medical practitioners, and, of course, it would not be thus singularly popular did it not supply a want and fill a place."

Freeman's Original Chlorodyne

engraved on the Government stamp outside every bottle. Sold by the Inventor and Manufacturer, R. FREEMAN, 79, Kennington Park Road, London, S., and most Chemists. In bottles, ½ oz., 1s. 1½d.; 1½ oz., 2s. 9d.; 10 oz., 11s.; 20 oz., 20s.

Caution! Beware of spurious, deceptive, and dangerous imitations. Ask for Freeman's Original Chlorodyne, and see that you have none other. [10

Gathered from the Waters.

For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1837, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,000 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C. [22

FRANCIS RAVENSCROFT, *Manager.* [18

The Planet Permanent Building and Investment Society,

Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and all further information may be had of EDMUND W. RICHARDSON, Secretary.

Prew and the Fine Weather.

The weather continues remarkably fair;
The poor and the wealthy its influence share;
Delightful excursions by sea and by land,
And summer enjoyments, are everywhere planned.
PREW'S elegant clothing we never should miss
At a beautiful season of sunshine like this.
Whatever new garment you purpose to buy,
B. PREW at his "Wardrobe" can daily supply.
The Capes and the Overcoats, faultlessly made,
In novel and various styles are displayed;
In light woven fabrics the garments appear,
All neatly designed for the time of the year:
The Press Coats and Frock Coats, as all will admit,
Are perfect in quality, fashion, and fit;
And the Waistcoats and Trousers, in novel display,
Are termed the most beautiful styles of the day.
With equal approval each purchaser views
The JUVENILE CLOTHING at BENJAMIN PREW'S.
The styles are exceedingly novel and neat,
And parents acknowledge the fashions complete;
And be it remembered that savings are made
By parties who patronise PREW in his trade.

Liveries, &c. Always a choice from 2,000 Children's Knickerbocker suits, from 12s. 6d.

B. PREW, Practical Tailor and Juvenile Outfitter. The Great Metropolitan Wardrobe, 294 and 295, High Holborn, fifteen doors west of Chancery Lane. [21

Magic Portraiture.—To be

enabled to produce your OWN PORTRAIT by Magic Photography, with a few drops of water only, causing endless fun and amusement, send your carte de visite and 30 stamps to Messrs. ANGERERS, SON, FRUWIRTH, and Co., 146, Cheapside, E.C. One dozen with materials and printed directions for instantaneous production will be returned with the original within ten days. [31

Hall's "Lung Restorer"

gives instant relief in Coughs, Asthma, Hoarseness, Sore Throat, &c. Mr. R. Brooke, Mirfield, near Leeds, writes, after suffering over ten years with an asthmatic cough, "Three 1s. 1½d. bottles cured me." Prepared by THOMAS HALL, Chemist, 5, Commercial Street (City side Great Eastern Terminus), London, and sold by all Chemists, in bottles, at 1s. 1½d., 2s. 9d., &c. [32

Gout or Rheumatism is

quickly relieved and cured in a few days by that celebrated medicine, BLAIR'S GOUT AND RHEUMATIC PILLS. Sold by all Medicine Vendors, at 1s. 1½d. and 2s. 9d. per box, or obtained through any Chemist. [33

THE PIANOFORTE MANUFACTURE.

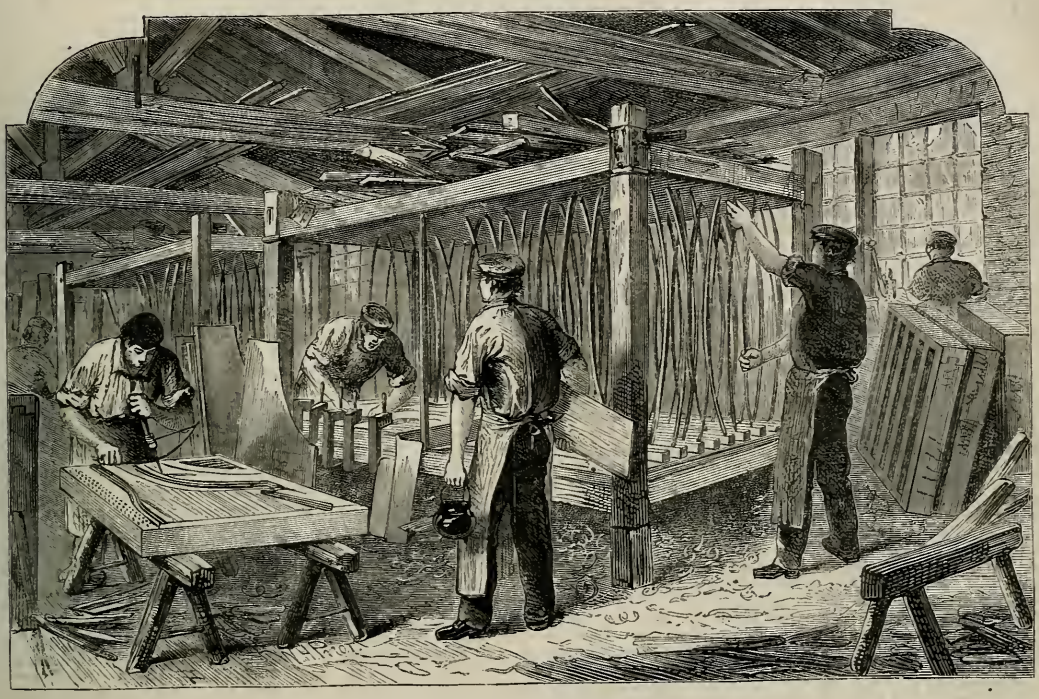

FIG. 1.—MAKING SOUNDING-BOARDS.

FIG. 2.—THE KEY-MAKER'S SHOP.

FIG. 3.—THE STRINGING-ROOM.

MR. C. CADBY'S
Gray's Inn Pianoforte Manufactory,
LIQUORPOND STREET, LONDON.

"Music for the Million!" is an announcement with which the public were made familiar some years ago, when a reviving taste for musical education rendered publishers and others anxious to supply the popular demand for the means by which it could be acquired. We have made rapid progress, as a nation, in musical culture even since that recent time. We have seen music introduced as one of the branches of instruction in our most elementary schools; glee-clubs and part-singing associations, largely composed of working men, established all over the country; and bands of efficient singers gathered together from the people, which have made possible such superb performances as those of our Handel Festivals, the Festivals of the Three Choirs, &c. Moreover, the taste for instrumental music has kept pace with the education of the voice—the one, indeed, naturally fostering and encouraging the other. So that we have come to look upon it as a matter of course that in almost every family one or more of its members should possess a musical instrument—it may be the humble flute or concertina, the more aspiring violin, or probably that best of instruments and universal favourite, the piano.

But "Pianos for the Million!" We should scarcely have expected to see such an announcement as this, and yet it is, in effect, that which meets our eye as often as we look through the advertising columns of the daily papers. So many improvements have been made in the manufacture of pianos during the last few years, so many methods have been found to cheapen the cost of production, and so large a demand for the instrument has arisen, enabling the manufacturer to sell at a small profit, that the price of a good piano is now little more than one-half what it would have cost twenty or thirty years ago, and the instrument itself is much better in quality. No wonder that the piano is finding its way even into the homes of our artisans, many of whom are rapidly becoming equal, in musical taste and culture, to those of France and Germany.

Having a desire to witness the processes by which pianofortes are manufactured, we recently visited one of the large metropolitan establishments—that of Mr. C. Cadby's, in Liquorpond Street. This establishment, we were informed, presented peculiar facilities for becoming acquainted with the subject, inasmuch as nearly every part of the manufacture is carried on in his extensive premises. From the rough wood to the perfect instrument, pianos can here be seen in every stage, and all the details by which the one is transformed into the other can therefore be witnessed by the observer.

By the favour of the proprietor we were afforded every opportunity to inspect the manufactory, and, taking the processes in order, were conducted, in the first instance, into the yard where the huge piles of timber of all kinds are stacked for future use. Ash, beech, pine, deal, rosewood, mahogany, walnut, &c.—all the woodwork for the body and more substantial parts of the piano—here lay in planks, pile above pile, but crosswise, so that every separate plank could become thoroughly exposed to the action of the atmosphere, and be thus properly seasoned before being made up. Usually the wood remains out in this fashion for two or three years, after which it is taken into a dry store-room close by. The more costly kinds of wood—mahogany, rosewood, walnut, &c.—used for the ornamental work, occupy the centre of this room; and some of this, as well as of the inferior kinds, is frequently kept in store as long as seven or eight years, that it may become so perfectly seasoned that the pianos manufactured from it shall be fitted for export to any climate.

Above the large timber store-room is another, used for veneers alone, where, in a small compass, more than 100,000 feet are kept. Some of these veneers of walnut and other valuable woods consist of slices so thin that twenty-eight go to the inch. In the general storekeeper's room near at hand is kept the beautiful fret-work used for the fronts of pianos. Each fret is formed of three separate veneers, so joined as to impart to the whole a strength far beyond what would be expected from its light and delicate appearance. Also dozens of beautiful carved truss legs and fronts, always ready, with all the action-works suitable for completing the piano; and from this room are the workmen supplied daily for each of their requirements.

We pass from the store-rooms to the machinery department, where the wood we have seen is cut up into the various forms adapted to the purposes required. Here we see solid blocks dealt with by those two powerful agents, steam and steel, as if they were so much cheese, and marvel at the ease and dexterity with which the processes of sawing, planing, &c., are performed. To produce the power required, a "donkey" is employed—not a quadruped, but an engine—to fill the boiler; also, a twenty-five horse-power engine, to keep in motion sawing, planing, turning, morticing, tenoning, moulding, drilling, and other machines.

The "back-making room" is the first in which the process of construction actually commences. Here the framework of the piano is put together, and the work must be of the most solid description, for the strain upon many parts of the piano when it is being played is enormous. It is said that the average strain of each string of a full-sized or grand instrument is about fifty-seven pounds. To resist this strain, five or six thicknesses of timber are used in the construction, the grain of each piece crossing that of the next, and the whole joined together with strong glue and immense pressure, in the manner of veneer. In this and other rooms the glue is made ready for use by steam-pipes, which obviate the danger and inconvenience of the use of fires.

In the "small workers' room," all the inside action of the piano is prepared. What is termed the action is, of course, the beautiful and ingenious mechanism by which the tones of the instrument are produced. Our readers who have seen the inside of a piano are aware that the wire strings are put in vibration by means of small hammers, connected by levers with the keys or finger-board. The hammer quits the string directly it is struck, and a "damper" falls down upon the wire, and stops its vibration, the moment the finger quits the key. The hammer shanks are formed of cedar-wood and covered with felt and leather, while that portion of the damper which falls upon the string consists of felt. The making of the "action" is a work of delicate nature, as the various parts require very careful adjustment. Mr. C. Cadby makes many of his pianos with the patent iron truss bracing, so much sought after for the foreign trade.

We now come to the key-makers' shop (Fig. 2), and notice with what care the thin white layers of ivory, which form the tops and fronts of the keys, are fixed upon their wooden foundations. The black keys are formed of ebony; and when the whole key-board is ready, its divisions are sawn through, as seen in our engraving, and it is then finally polished.

The preparation of the sounding-board is an operation requiring the greatest skill, as the thickness of the board itself diminishes by the finest possible gradations, according to the length of the strings to be attached. The room in which the sounding-boards are made ready is shown in Fig. i. In the centre of this shop the various portions are kept in racks to become thoroughly dry before use; and down the sides the processes of preparing are carried on. In the left of our illustration, a workman is seen drilling the holes in which the wrest pins for the strings are to be inserted.

The sounding-board finished in this way, it passes on to the "stringing-room" (Fig. 3). The wire for the strings is made ready in the workshop shown in Fig. 4, and is kept in coils of various sizes or thickness. The thinner strings are used for the higher notes; for the lower or bass notes the strings are coated with copper wire.

We have now seen the various portions of the piano made ready for fitting into the case, but have yet to witness an interesting department of the work by which the case itself is prepared. We allude to the making of the veneers which ornament the fronts of the instruments, and give them their handsome appearance. The thin slices of walnut and other woods which we saw in the store-room, have to undergo a deal of delicate manipulation before they are ready for use. The walnut, for instance, are anything but those perfect planks which the uninitiated might have expected to see. They are, in fact, cut from the excrescences of the tree, and are therefore full of holes and defects, which have to be filled in and rectified in the most ingenious and artistic manner. When the entire and complete surface is obtained, the veneer is ready for affixing to the case, and the piano then shortly becomes a finished instrument. As such it takes its place among its fellows in the spacious show-rooms of the house.

We have seen much to interest us in this establishment, but can only give the reader a sketch of its principal features. Mr. C. Cadby employs altogether about 150 hands, and has frequently on his premises as many as from 500 to 600 pianos in various stages. We are gratified to learn that he was awarded a first-class prize medal for the excellence of his instruments at the Great Exhibition of 1862.

It may be interesting to know that the first man ever employed at the formation of this business, is still to be seen on the premises. Many are there of eighteen and twenty years' standing—creditable to the workman as to the employer.

*Government Life Insurance.**

We proceed with the further development of the system of insurance which we have undertaken to recommend to our readers, for their adoption and benefit.

And, first, it will be both convenient and useful to summarise the several forms under which, by the Act 27 and 28 Vict., c. 43, the Postmaster-General is empowered to enter into present and prospective engagements with persons of either sex, between the ages of sixteen and sixty, relative to life insurance and the granting of annuities.

LIFE INSURANCE FOR AMOUNTS RANGING BETWEEN £20 AND £100, PAYABLE AT DEATH:—

1. By payment of a *single* premium.
2. By payment of an *annual* premium throughout life.
3. By payment of a premium once every *half-year, quarter, month,* or *fortnight,* throughout life.
4. By payment of an *annual* premium, ceasing at sixty years of age.
5. By payment of a premium once every *half-year, quarter, month,* or *fortnight,* ceasing at sixty years of age.

LIFE ANNUITIES OF NOT LESS THAN £1 AND NOT MORE THAN £50:—

1. By a *single* payment to purchase an *immediate* annuity payable half-yearly.
2. By a *single* payment to purchase a *deferred* annuity, payable half-yearly, and to commence at a given age.
3. By an *annual* payment, ceasing at a given age, to purchase a *deferred* annuity, payable half-yearly and commencing at that age.
4. By a *half-yearly, quarterly, monthly,* or *fortnightly* payment, ceasing at a given age, to purchase a *deferred monthly allowance* of not less than 4s. or more than £4 3s. 4d., to commence at that age.

For all these transactions there is the full security of the Government for the payment of the money directly it is due, and all the premiums are calculated upon a basis which secures this advantage at the cheapest rate consistent with safety to the national exchequer.

The following example will illustrate generally the various ways in which Life Insurance can be effected:—

The life of a man or woman in his or her thirtieth year may be insured for £100—	£	s.	d.
1. By a *single* payment of	43	3	7
2. By an *annual* payment, throughout life, of .	2	6	7
3. By a *quarterly* payment, throughout life, of	0	13	0
4. By a *monthly* payment, throughout life, of	0	4	4
5. By a *fortnightly* payment, throughout life, of	0	2	2
6. By an *annual* payment, until the insured person reaches the age of sixty, of . .	2	13	10
7. By a *quarterly* payment, until the insured person reaches the age of sixty, of . .	0	15	0
8. By a *monthly* payment, until the insured person reaches the age of sixty, of . .	0	5	0
9. By a *fortnightly* payment of . . .	0	2	6

The premiums, of course, vary according to the age of the person who wishes to insure his life, and smaller sums can be insured by proportionate payments. Thus, at the age of 30, a payment of 2s. a month throughout life will provide £46 1s. 10d. at death.

One most important feature of the Government Insurance system is that all sums insured are payable to the proper representatives *immediately on proof of the death, even though that should occur directly after the first premium has been paid.* In ordinary insurance offices it rarely happens

* Continued from page 252.

that the sum insured is paid much within six months after death, and great inconvenience and distress often result from this delay.

Again, if a person has been insured for five years, and either from ill health, want of work, or any other cause, he is unable or unwilling to continue his premiums, the Postmaster-General will return him a certain fixed proportion of the money he has paid, retaining only such a sum as will cover the risk which the office has borne whilst the insurance lasted.

Such important points as these distinguish the Government Insurance from all other; and, indeed, until Mr. Gladstone took the matter in hand, insurance for any sum below £100, or by more frequent payments of premium than every quarter, was almost entirely unrecognised. The premium to insure a given sum will necessarily be less in amount if paid once a year, than if it were paid by instalments twelve or twenty-four times in a year, because of the additional trouble and expense involved in the frequent collection of the money. Indeed, the most advantageous form of insurance, both to the office and to the person insuring, is that in which by one single premium a given sum is insured. Thus, if two men, both aged 24, effect an insurance for £100, the one by paying a single premium of £39 6s. 6d., and the other by paying an annual premium of £1 19s. 10d., the single premium would contain a provision for office expenses of 15s. 5d., whilst the same provision for each of the annual premiums would be 3s. 7d. So, if both persons lived to 60 years of age, he whose £100 was insured by the single premium, would have paid only 15s. 5d. towards office expenses, whilst the other would have paid no less than £6 9s. towards such expense.

Here, then, it is that the Post-office Savings Bank is so excellent an auxiliary to the Insurance Office, inasmuch as a person may, as often as he is able, deposit small sums in the Savings Bank until he feels quite certain that the money will not be wanted for immediate use; and he can then apply it to the insurance of his life by a single premium. The money is transferred from the Savings Bank to the Insurance Office books, and thus the trouble and risk of drawing cash out of one account and paying it into another is avoided.

The insurance by single premium especially commends itself to those who are uncertain of their future prospects, and are consequently debarred from engaging themselves to pay regular premiums at fixed intervals, but who would be willing to apply towards the insurance of their lives, from time to time, such sums as they may be able to save, or of which they may become possessed. And it should be noted that persons who commence by insuring for a small sum may increase their insurance whenever they are in a position to do so, until the aggregate amount reaches £100. Moreover, in the case of a married couple, both husband and wife may each be insured for £100.

The following tables show the different rates of premium charged under the various applications of life insurance, and we are in a position to state that those rates are lower than are charged by offices doing the largest amount of business amongst the provident working men.

TABLE 1.

Age next Birthday.	Sums which may be Insured by the Payment of the Undermentioned Single Premiums.														
	£20			£30			£40			£50			£100		
	Single Premiums.														
	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.	£	s.	d.
17	7	2	8	10	13	0	14	3	4	17	11	8	35	3	5
18	7	5	3	10	16	10	14	8	5	17	18	0	35	16	1
19	7	7	8	11	0	6	14	13	4	18	4	2	36	8	4
20	7	10	1	11	4	1	14	18	1	18	10	1	37	0	2
21	7	12	4	11	7	5	15	2	7	18	15	9	37	11	5
22	7	14	7	11	10	11	15	7	2	19	1	5	38	2	11
23	7	16	11	11	14	5	15	11	10	19	7	3	38	14	7
24	7	19	4	11	18	0	15	16	7	19	13	3	39	6	6
25	8	1	9	12	1	7	16	1	6	19	19	4	39	18	8
26	8	4	3	12	5	4	16	6	5	20	5	6	40	11	1
27	8	6	9	12	9	2	16	11	6	20	11	11	41	3	9
28	8	9	4	12	13	0	16	16	8	20	18	4	41	16	9
29	8	12	0	12	17	0	17	2	0	21	5	0	42	10	0
30	8	14	9	13	1	1	17	7	5	21	11	10	43	3	7

Under the foregoing Table, a person may commence by insuring his life for £20, and may increase his insurance from time to time, either by smaller or larger sums, until his aggregate insurance amounts to £100. Thus, if at age seventeen he secures £20 by paying £7 2s. 8d., he can, at age twenty, insure for another £10, by paying £3 16s. 1d., and at age twenty-five for a further sum of £5, by a premium of £2 2s.; so that altogether he will have paid £13 0s. 9d. in premiums, and will have secured for his family £35, payable at his death.

TABLE 2.

Age next Birthday.	£100 at Death may be secured by paying the Annual Premiums as under.	By Paying £1 a Year the following Sums at Death may be secured.	By paying 2s. a Month the following sums at Death may be secured.
	Annual Premium.	Sums Insured.	Sums Insured.
	£ s. d.	£ s. d.	£ s. d.
17	1 13 6	59 15 6	64 6 0
18	1 14 5	58 3 5	62 11 2
19	1 15 4	56 13 5	60 18 8
20	1 16 2	55 5 7	59 8 5
21	1 17 1	53 19 9	58 0 6
22	1 18 0	52 14 3	56 12 10
23	1 18 11	51 9 1	55 5 7
24	1 19 10	50 4 2	53 18 7
25	2 0 10	48 19 6	52 11 10
26	2 1 11	47 15 1	51 5 4
27	2 3 0	46 10 11	49 19 1
28	2 4 1	45 6 11	48 13 1
29	2 5 4	44 3 2	47 7 4
30	2 6 7	42 19 7	46 1 10

The premiums for smaller sums can be easily computed from the above Table. Thus, at age twenty, the annual premium to secure £100 is £1 16s. 2d.; half that premium (18s. 1d.) would secure half the amount (£50), and so in like manner for other sums. The same rule holds good with the other two columns of the Table, and the principle of progressive insurance is applicable in each case.

TABLE 3.

Age next Birthday.	£100 at Death may be secured by paying Annual Premiums as under until the assured Person reaches the Age of 60 Years, if he live so long.	By paying 2s. a Month until the Age of 60, if the assured Person lives so long, the under-mentioned Sums at Death, whether before or after 60, may be secured.
	Annual Premium.	Sums Insured.
	£ s. d.	£ s. d.
17	1 16 1	59 14 5
18	1 17 3	57 17 11
19	1 18 4	56 3 7
20	1 19 6	54 11 4
21	2 0 7	53 1 2
22	2 1 10	51 11 2
23	2 3 0	50 1 6
24	2 4 4	48 12 1
25	2 5 8	47 2 11
26	2 7 2	45 13 10
27	2 8 8	44 5 0
28	2 10 4	42 16 3
29	2 12 0	41 7 8
30	2 13 10	39 19 4

By this arrangement the premiums are payable until the person insured attains sixty years of age, when they are discontinued—the sum insured being payable at his death; and if he should die before he is sixty, the sum insured will equally be paid at his death. This plan is advantageous to those whose earnings depend upon their power of work, which declines with advancing age, and thus renders them less able to keep up the payments of premium.

BIRMINGHAM purchases for manufacturing purposes 26,000 tons of copper per annum. She uses this quantity somewhat in the following manner:—say 7,000 tons for making yellow metal, 6,000 tons for making tubes of copper and brass, 4,000 tons for making wire, and about 3,000 tons for making brass and other metallic mixtures.

LIGHTING OF PUBLIC HALLS BY MAGNESIUM.—At the Royal Institution recently, Mr. Larkins exhibited his method of illuminating public halls by the combustion of magnesium. The magnesium, in a finely divided state, is showered on small flames of gas, and thus produces a brilliant illumination. It was the first time the apparatus had been publicly exhibited. The flame was flickering, but the pure quality of the light contrasted strongly with the usual gas flames of the burners in the lecture theatre.

"*Up in the Morning Early.*"

I REMEMBER hearing a song, the subject of which was a lover meeting his lass early in the morning, and pressing his suit till the eventful "Yes" was bashfully uttered. The singer had a good, clear, baritone voice, and right merrily trolled the burden of the verse—

> "Young maidens, they say,
> Will seldom say Nay,
> If asked in the morning early."

There is an influence in the balmy breath of the early day which appears to make the heart more susceptible of joyous, tender and innocent emotions. Two or three centuries ago, when life was less artificial than it is now, English girls used to be up betimes, and in the bright mornings of the young summer bathe their faces in the dew to freshen their complexions. They went to bed early, and had three hours of "beauty sleep," as the old folks call sleep before midnight, and early in the morning, when "up rose the sun and up rose Emily," as one of our old poets sings, they were as fresh-looking as the daisies and as cheerful as the birds twittering or in full-voiced song in the trees and bushes. Then the run over the dewy meadows, and the "mouthful of fresh air," which is the best tonic in the world, heightened the roses on their cheeks; and I cannot wonder if the lads who were up betimes too, and about their early work, stepped nimbly after their blooming sweethearts, and, pointing to the little spire of the village church, so clear and sharp against the golden sky, did not wait long for the dear "yes," which made them think that the early sunshine was a perpetual glory.

Ah, me! many of us have seen such a morning as that. With some it has been followed by a sunny noon, and evening shades closing sweetly on the scene; others have seen the sky clouded with storms, and drifting on to dark and dismal nights. But the memory of the old golden mornings lives still; and, as children are born every day to remind us what beauty and innocence there is in the essence of humanity, so, in each succeeding summer time, are early sunshine and the rejoicing of all created things.

These thoughts come into my head when I am going to work these fine summer mornings. My way lies through the streets of this mighty London. The shadows on the path are not those of tall elms or branching oaks; there are no wayside flowers. But the sun shines very brightly; the air is infinitely clearer than late risers will believe to be possible; and the sweet perfume of the hay is borne into the heart of the big town, though the fields where the mowers have been at work for the last hour or more lie miles away in Kent or Surrey. It was on just such a morning as this that, years ago, Nelly placed her hand in mine as we stood by the gate of a corn-field (I was a country apprentice then), and the sky of our future life seemed to be as flecked with golden hope as the blue vault above us was with the rays of the morning sun. On many such mornings as this—Sunday mornings—I have walked to a little "God's acre," miles away, where lies a faded blossom of our lives, gathered into the sheaf by the reaper Death.

Some places, perhaps, like the "fair Melrose" of Sir Walter Scott, are seen to best advantage by "the pale moonlight;" but London never looks so well as at four or five o'clock on a summer's morning. I don't go to work quite so early as that, but I am often out of bed and enjoying a walk. Sometimes I go to the early markets, where the market carts are discharging their loads of fresh vegetables from Brentford or Fulham, or the baskets of fruit from the Kentish orchards. Sometimes I stroll on to one of the bridges; and if any one wants to know how beautiful big London can look, he could scarcely choose a better spot for a good view. The river literally smiles in the sunshine streaking the ripples of the stream. It is difficult to believe in the murky stream of mid-day. The sails of the vessels seem bright and clear; no smoke hangs in the air; and the roofs of the houses glisten in the clear light. The outlines of the buildings are sharply defined, without that blur of indistinctness which the vapours of an hour or two hence will create. The hundred or more spires stand out against the sky, some white and new, others time-worn and dull in tint, but all combining to make up a beautiful and varied picture. Above all is the giant dome,

every rib and moulding visible, with the golden cross high in air, shining like a beacon.

There are not many people in the streets, but there are enough to give one a strange insight into the varied conditions of humanity to be met with in a great city. The cheerful features of the scene are the men hastening to work, stepping along with firm tread, stopping, perhaps, to enjoy a cup of coffee at the stall at the street-corner; the light carts hurrying with the morning's newspapers to the railway stations; fresh-faced, cosy-looking butchers, greengrocers, and fishmongers on their way to market; early postmen hurrying to sort and deliver the morning mails; a few holiday-makers, all agog with delight, and promising themselves unheard-of pleasures if they reach the early Parliamentary train in time. There are water-cress women, sad looking and weary, even at these small hours of the day, anxious to earn a breakfast for the little ones by a morning's toil. Some carry babies slung at their backs, and some have little ones dragging at their ragged skirts. There are flower-girls going to purchase moss-roses and geraniums, lilies of the valley and pansies, for bouquets. The night-cabman rouses himself on his box, or shakes himself out of the cab, where he has been enjoying a nap, and prepares to drive home to the stable; and the night-policeman casts his eyes up to the church-clock, and wishes the morning men would come on. The bakers, who have had a few short hours of rest, were up again two hours since, and we do not see their thin figures and white faces, for they are now busy drawing hot batches, and preparing the oven for the eight o'clock rolls.

From under archways and from off door-steps, from the pavement outside the huge buildings—paid for liberally to shelter the houseless poor, but barricaded like fortresses against the shivering wretches whom abject poverty has not quite deprived of decency, and who would prefer to perish in the streets to encountering the abomination and degradation of the casual ward—creep shivering wretches, old and young, ragged and dirty, cold and hungry, to prowl again in the streets of the great inhospitable London. They are not all good and persecuted. There are born thieves and vagabonds among them, ribald wenches who have crouched all night on park benches or in dark passages, and now sit down on the edge of the kerb and twist up their tangled hair, and interchange coarse jests and blatant profanity. There are skulking lads tramping into London after a round of the Essex or Hertfordshire union-houses, perhaps after a visit to sundry county gaols.

There are other scenes, not of regular, but occasional occurrence; such as the trooping of crowds to secure good places to see a wretch expiate his crime on the scaffold. Sometimes, too, a mob of yelling, foul-mouthed fellows, the scum of the back slums of the East and West Ends, meet at a railway station, and are joined by well-dressed men, who arrive in Hansom cabs, and are politely waited on by railway authorities, who are willing (wealthy and respectable though the great companies they represent are presumed to be) to furnish special trains for the accommodation of patrician and plebeian ruffians who delight, in defiance of the law, in seeing two brawny gladiators beat each other.

Such things, some pleasant and cheering, others painful and repulsive, may be witnessed by him who, wishing to see London at its best, gets "up in the morning early."

Anthracite Coal.—When the anthracite coal up the Schuylkill at Mount Carbon was first effectively discovered, no way of igniting it was known, and it was deemed of little value until an English chemist in 1810 erected a furnace, and with three strong bellows succeeded in bringing out such an intense white heat from the coal as to melt platina. It then came into general use

The Utility of Petitions.

Petitioning has fallen into disrepute of late years, partly through misapprehension of its uses, and partly through political disappointment. Petitioning is an ancient English right, and used to be highly valued. It has lost none of its value, though it has suffered in reputation. Years ago numerous petitions were presented to the House of Commons in favour of political reform. They were not much attended to, and were ordered "to lie upon the table," and were not much heard of afterwards. Naturally, though not wisely, a reaction grew up against petitioning; and now, when Parliament is more disposed than ever to attend to the wishes of the working classes, many questions are delayed, neglected, and suffer, in Parliamentary opinion, from not being supported by petitions.

There are two kinds of Bills commonly brought into the Houses of Parliament—public Bills and private Bills. Public Bills relate to the whole community; private Bills are such as enable individuals, public companies, or corporations to do certain things which affect only a portion of the public, a particular town or place. Petitions are differently treated, accordingly as they relate to public Bills or private Bills. Those affecting public Bills are presented publicly by a member, in his place in Parliament; and he may state the object of a petition; who signs it; explain whether it is influentially or numerously signed; may read its prayer or principal allegations: but a petition relating to a private Bill requires to be brought under the notice of the committee whose business it is to consider the private Bill, and this is done through the agents opposing the Bill, and the petition does not come before Parliament except in some report of the proceedings of the committee of the Bill. When the Victoria Park people lately petitioned against the threatened gas-works in their quarter, they were disappointed that their petition did not, like other petitions, come before Parliament. We have now stated the reason why. But it was in the power of the petitioners to have given their petition a public form, and have asked for protection against gas companies in the name of the general public, or as part of the general public, who might suffer in any or all places, by any inconsiderate introduction of gas-works, and solicited the general attention of Parliament to the general interests of the public. A petition so worded would become a public petition, and be publicly received.

When a stranger hears petitions presented with rapidity, and sees them crammed into the Clerk's bag, he finds that they do not even "lie upon the table" many minutes, but are bagged and carried away into unknown regions at once. This gives the impression that petitions are so much trouble wasted; but this is not quite so. There is a committee who have charge of all petitions, and a careful record is made of every petition, its object, whence and from whom it comes, and, in many cases, a careful abstract of it is made by some one, and all these facts are printed and sent round to every member's residence, that he may be kept acquainted with the demands, wishes, claims, or complaints of the public, on whose behalf and in whose name he legislates. When petitions relate to new Bills before the House, the chief petitions on both sides—that is, for and against measures in question—are printed and sent round to members in the same way; and when the Bills come on for debate, these petitions are consulted by members, who learn from them (if the petitions are well drawn and argumentatively expressed) more of the merits or demerits of proposed Acts of Parliament than can be elsewhere obtained. In these petitions private individuals can speak, and reasons which the proposers of Bills do not know, or often conceal if they do know, are thus brought under the notice of all the members who choose to look for them. There is, therefore, great utility in petitioning. Moreover, members who never read the petitions, count them. They ask, Are there any petitions about such and such a Bill? Does any one ask for it, or protest against it? and they judge in this way whether there is any, or what amount of public feeling upon any given question. To working men especially the right of petition is of no mean importance.

Petitions are the only modes open to the common people for being heard individually. The humblest person in the realm can thus bring his views before the highest assembly in the nation, and can be heard there. Any man or woman may petition the House of Commons or Lords. Whoever suffers grievance or wrong, or wishes to see a certain policy prevail, can thus become his own member of Parliament, and represent himself, and can state his own case, in his own way, and in his own words. For instance, there was a remarkable petition presented the other day by Mr. Alderman Cowen, the member for Newcastle-upon-Tyne, from some working men's political union in the town of Newcastle-upon-Tyne, which stated that they felt that exclusion from the franchise was a personal degradation. They neither based their petition for Reform upon rights of man, nor rights of property, nor rights of intelligence, but upon the manlier ground of self-respect. They stated that they felt exclusion to be a personal humiliation, and that they wished for enfranchisement as a means of discharging their public and political duty. Of all the petitions presented to Parliament, and they have been legion of late, this was the only one which took this remarkable ground. It is thus that petitioning is a personal privilege and a useful opportunity, valuable to working men, and one which they would be able to turn to a very useful and advantageous account if they understood it, for there are more conscientious members in the House of Commons than formerly, who do give attention to the allegations of petitioners and memorialists.

CIRCULAR DESIGN.

The Artist Workman.

CIRCULAR DESIGN.

In the illustration given by us this week, the details of the ornament are well proportioned, and form a harmonious whole. The grouping of the parts is very effectively arranged, and might be studied with advantage by our artist workman. It will be seen that the design is simply a series of repetitions of a portion of the whole. This is called "point" design, and more commonly practised than any other.

PIANOFORTE MAKING.—FIG. 4. THE WIRE-WORKERS. (*See page* 370.)

*Lessons in Mechanics.**

In the preceding lessons I have shown how work done by men or animals may be measured and compared with other kinds of work; and I have also distinguished between the work of which an agent is capable, and the work actually done by that agent, which is called "useful work."

In fact, "to do work" is "to overcome or destroy resistance," and the resistances overcome or destroyed arise from the adhesion of the molecules of bodies, the force of springs, the force of gravity, the inertia of matter, and a thousand such other causes. Thus, to polish a surface by friction, to break stones, to lift weights, to throw stones, &c., is to overcome, during a certain time, resistances incessantly renewed during that time.

Mechanical work does not imply merely a resistance overcome, once for all, or equilibrated by a motor force, but it implies *a resistance constantly destroyed along the path described by the point of application, and exerted in the direction itself of that path.*

Thus, to lift with a shovel a portion of clay from the ground, we must not only make an effort in a *vertical* direction equal to the weight of the clay, but we must cause this weight or resistance to move in the vertical direction; and the work actually done is proportional to the height through which the weight is lifted; if the height be double, the work is double, and so on. In like manner, the work is double if the weight be double, and so on; and thus the total work done is measured by the product of the weight and height; for as it varies proportionally as each of these quantities, it will vary as their joint product.

If, instead of lifting a weight, a man or horse draw a load along a horizontal road, the work done in this case is measured on precisely the same principles. We are to find the pull on the traces and the length of the road, and the joint product of both will give the work done, for the resistance overcome or work done is proportional directly to the pull on the traces, and also to the length of the road, and, therefore, the total work varies as the product of both.

In both these cases the useful work is expressed properly by an equivalent weight multiplied by the height to which it is supposed to be lifted, although in the horizontal transport of weights engineers are too frequently content with stating the actual weight transported a given distance horizontally. I have already fully shown that this may be converted into weight actually lifted by dividing it by 25, which represents for men and horses, on a level road, the proportion of weight to traction.

The work done in any description of labour ought always to be converted into a weight lifted through a height, which is the natural measure of work. When a millwright says that a pair of stones will grind so much corn per hour, he does not speak so as to be intelligible even to other millwrights, unless he specify the description of corn, and its condition at the time of grinding, as to moisture, &c. When a Cornish engineer tells us that the stamping machinery at Polberro stamped 30,201 tons of tin ore in the year 1854, we cannot form an opinion as to the amount of work actually done without knowing the hardness and tenacity and other qualities of the ore acted upon. On the other hand, when he informs us that the machinery consists of 72 stampers, weighing each 600 lb., which are lifted 9 inches, and make on an average 45 blows per minute, then we can easily calculate the amount of work applied, and ascertain how much is necessary for the crushing and stamping of the tin ore employed:—

$$\text{The work done per minute} = \frac{72 \times 600 \times \frac{3}{4} \times 45}{2240} = 651 \text{ ft.-tons.}$$

This is equal to the daily work of two strong men, and is expended during each minute that the stamps are in action.

The work done is also equal to 1458000 ft.-lb., which may be converted into horse-power (steam), by dividing by 33000, the number of ft.-lb. of work done by Watt's steam-horse in one minute:—

$$\text{Work of stamps at Polberro } \frac{1458000}{33000} = 44 \text{ horse-power.}$$

The engine that did this work was a 36-inch cylinder engine, working at 55 horse-power; and the useful work done was, as I have shown, 44 horse-power; from which we may infer that one-fifth of the work applied was destroyed by the friction of the machinery necessarily used.

The following amounts of tin ore were crushed by this engine:—

In 1854	. . .	30,201 tons.
1855	. . .	29,663 ,,
1856	. . .	31,411 ,,
Mean	. .	30,425 tons per annum.
		585 tons per week.

Allowing six working days per week, this result is very nearly 100 tons per day, stamped by 72 stampers, or exactly 1·354 tons per day to each stamp. At Great Hewas mine the ore is so different in texture and toughness, that 3 tons per day can readily be crushed by a similar stamp-head.

It is evident from the preceding examples that it is unscientific, although sometimes convenient, to express work done in units of bushels of barley ground, tons of tin-stuff stamped, &c., or, in fact, in any other units of work than those suggested to us naturally by the force of gravity, which draws every substance and being on the surface of the globe towards the great mother earth, with a constant, gentle, and easily-measured force.

Every description of work done, or resistance overcome, may be ultimately reduced to a certain weight lifted through a certain height, and the product of that weight by that height is the only accurate or admissible measure of the amount of work expended.

For example: in order to show the complication really inherent in several industrial occupations, I shall use the case of the iron-filer, who must—1, exert a certain pressure to make the file bite; 2, make the file slide along the body filed, by the exertion of a certain force, acting with a certain velocity; 3, bring back the file to its former place, with a certain velocity, and so overcome the inertia of the file. The quantity of work actually done by the workman is the sum of the three foregoing works, of which the first and third are only fatigue work, and the second only is useful work. If it were our object to calculate, for physiological purposes, the whole work done by the labourer, we should be obliged to estimate Nos. 1 and 3, as well as No. 2; but if we only want to know the useful work done, we can calculate No. 2, by supposing that the workman was only obliged to push his file, loaded with a weight sufficient to make it bite, with a uniform movement continued in the same direction along a straight bar of metal placed horizontally. The amount of the horizontal push or thrust of the labourer may be expressed as a weight in pounds or tons, and this weight, multiplied by the total length of the path described by the biting file per day, will give the daily useful work employed in that description of labour.

The term "work" is now universally used in the sense of the joint product of the force applied to overcome a resistance, and the path described in the direction of the force. It corresponds to

* Continued from page 325.

other phrases used by older writers. Thus, Mr. Smeaton has called it "mechanical power," in his treatises on hydraulic wheels; M. Carnot calls it "moment of activity;" MM. Monge and Hachette name it "dynamical effect;" Messrs. Coulomb, Navier, and others speak of it as "quantity of action." The expression "work" (*travail mécanique*) was first introduced by Poncelet, to whose genius and writings the science of applied mechanics is so much indebted; and it has been adopted by mechanicians of all countries, as the most suitable term to express the stored-up or expended result of the application of a force for a certain time to overcome a resistance.

A MAN'S A MAN FOR A' THAT.

(*A New Version.*)

BY CHARLES MACKAY.

"A man's a man," says Robert Burns,
"For a' that and a' that;"
But though the song be clear and strong,
It lacks a note for a' that.
The lout who'd shirk his daily work,
Yet claim the wage and a' that,
Or beg, when he might earn, his bread,
Is *not* a man for a' that.

If all who dine on homely fare
Were true and brave, and a' that,
And none whose garb is "hodden grey"
Was fool or knave, and a' that,
The vice and crime that shame our time
Would fade and fail, and a' that,
And ploughmen be as good as kings,
And churls as earls for a' that.

You see yon brawny, blustering sot,
Who swaggers, swears, and a' that,
And thinks, because his strong right arm
Might fell an ox and a' that,
That he's as noble, man for man,
As duke or lord, and a' that;
He's but a brute, beyond dispute,
And *not* a man for a' that.

A man may own a large estate,
Have palace, park, and a' that,
And not for birth, but honest worth,
Be thrice a man for a' that;
And Donald, herding on the muir,
Who beats his wife, and a' that,
Be nothing but a rascal boor,
Nor half a man for a' that.

It comes to this, dear Robert Burns—
The truth is old, and a' that—
"The rank *is* but the guinea stamp,
The man's the gold for a' that."
And though you'd put the minted mark
On copper, brass, and a' that,
The lie is gross, the cheat is plain,
And will not pass for a' that.

For a' that and a' that,
'Tis soul and heart, and a' that,
That makes the king a gentleman,
And not his crown and a' that.
And man with man, if rich or poor,
The best he is, for a' that,
Who stands erect, in self-respect,
Who acts the man for a' that.

—*Blackwood's Magazine.*

DISTILLATION OF PLANTS.

Distillation, which is applied to plants, seeds, barks, woods, and a few flowers, consists in placing the substance from which the scent is to be extracted in a copper vessel called a still, with enough water to cover it. Heat is applied, and the steam generated, which is impregnated with the fragrant molecules, passes through the head of the still into the worm (a coiled pipe placed in a tube, where it becomes condensed by means of the surrounding water, which is constantly kept cool), issues in liquid form at the tap, and flows into the recipient. If sufficiently loaded with aroma, it then separates into two parts, the most concentrated of which, called the essential oil, collects either on the surface or at the bottom, according to its specific gravity. It is then decanted, and the water used again for distilling, unless it is of sufficient value in itself to be saved, as is the case with rose and orange-flower water. The recipient you see here is called a Florentine recipient, from its having been first used at Florence, where flower distilleries still exist. It is constructed in such a way as to allow the water to escape whilst retaining the essential oil. A great improvement has been lately effected in distillation, which consists in suspending the fragrant substance on a sieve in the still, and causing a jet of steam to pass through. This operation produces a finer essential oil than by allowing the substances to be steeped in water, as it only carries off the most delicate part of the aroma without dissolving the bitter principles frequently residing in the basis.

The fragrant principles of all aromatic plants may be extracted by distillation, in the shape of essential oil; in fact, it exists ready-formed in many of them, contained in minute vesicles, as you may see by bruising a thyme or rosemary leaf with the hand. Such is not the case with flowers; the aroma they possess, with a very few exceptions, is so fugitive that it would become destroyed in the process. In that case, maceration or absorption is resorted to. Maceration consists in steeping flowers in a bath of hot grease, letting them infuse for some time, and renewing them until the grease is completely saturated. This grease, which is called *pommade*, is then submitted to strong pressure in horse-hair bags. Oil is also perfumed in the same way, but requires less heat. This process is applied to rose, violet, cassie, jonquil, and orange flowers; but for more delicate flowers, such as jasmine and tuberose, the absorption or *enfleurage* system is employed. Purified grease is spread in a thin layer on a pane of glass mounted in a wooden frame or sash, called *châssis;* fresh flowers are strewed over this grease, and renewed every morning; and at the end of two or three weeks this grease or pommade acquires the scent of the flower in a high degree. Perfumed oil is made in the same way by substituting a wire bottom to the frame, and spreading on it a thick cotton cloth, steeped in the finest olive oil, which is pressed out of it after complete saturation. These frames are piled on each other to keep them hermetic.—*Eugene Rimmel on "The Commercial Uses of Flowers and Plants."*

AMONG THE SWISS CANTONS.

Mr. Joseph Fisher, in his recently-published work, "Where shall we get Meat?" thus describes Berne, one of the more celebrated of the Swiss Cantons:—

"Berne presents an aspect different from the other cantons; the buildings are much more massive. This arises from the fact that horses, cows, sheep, and pigs are all domiciled in the same house as the owner. They are usually edifices of three or four storeys high; one end is the residence of the family, at the other the horses, cattle, &c., are lodged on the ground floor, over which the hay, the corn, and the straw are kept. There are no haggards, no stacks of corn, no ricks of hay. Not a bit of litter is to be seen. The greatest care is taken of the dung and liquid manure. The former, when brought out from the stables, is piled up in a square heap. The straw at the ends is nicely turned in, and it is thus raised like a wall. It becomes perfectly decomposed, is never exposed to the atmosphere, and cuts down like a cheese. The liquid manure is all saved, and applied to the land in its due rotation. The farming is generally skilfully conducted, but an English eye is rather annoyed with the constant appearance of a plant like the dandelion, which the Swiss encourage, as they think it helps to increase the quantity of milk. The northern part of this canton is much less populous, and the farms are larger; the tillage has a less careful aspect. The good land of Berne forms a larger portion of its area than in Switzerland. It is thus classified:—

	Switzerland.	Berne.
Biens-fonds	7,640,350	1,253,000
Forests	1,980,000	292,000
Good lands	5,660,300	961,000

"Arable land is hardly a proper term, as there is included under the term 'good land' all the 'green Alps' or mountain pastures which cannot be tilled. It is easy to understand the reason of the Swiss for classing the forests among the *biens-fonds*, as it is from the former they derive their fuel. Except at the railway stations, coals are not seen, but wood is found everywhere. It is delivered in billets of about three feet long and about six inches square, which are to be seen in long piles outside the farmhouses; it is also thrown down from the carts outside the doors of the houses in the towns, where women and lads employ themselves in cutting it into lengths of about nine inches; these pieces are again split into billets of one and a-half to two inches square, in which shape they are removed into the store for use. Timber enters largely into the construction of the houses, but in the absence of slates they are almost universally covered with tiles. The projecting roofs, which sometimes run down to near the ground, afford shelter in winter and shade in summer. Some of the English residents have built houses after the style of their own country, but they look sadly out of place. Berne does not display the same activity as some other cantons, but is in a prosperous condition. Cattle are used for ploughing and carting; the vehicles are usually four-wheeled, and fitted with a break to prevent the too rapid descent of the hills."

Basle affords matter for a few notes:—"Basle is the best ventilated city I have visited in Switzerland; most of the others, though clean and well swept, are very unsavoury. Either the drains are defective, or they require flushing, for in some places, particularly Lucerne, the olfactory nerves were assailed in an unpleasant manner; even Berne, through the streets of which fresh water is always flowing, is not as sweet as could be desired for the health of the residents, or for the noses of the visitors. I went to the market at Basle; it was well supplied with a great variety of vegetables and fruits, but it did not present the active scene which I saw at Lyons. There was a large supply of cattle at market, and also of calves. The Swiss prefer veal to mutton, and more attention is paid to calves than to sheep. I noticed in Switzerland that which I did not see in France—a considerable cattle traffic on the railways. The calves, pigs, and some of the cows, were brought to market at Basle in low wagons, drawn by horses, and covered with canvas. The poultry were very nicely arranged; instead of being tied together by the legs, and put on a cart or into boxes, they were placed in round baskets, to the sides of which a net is attached, which was about two feet high, and closed with a running string like a bag; thus any of them could be taken out at a moment. The bridge at Basle consists of timber flooring; half of the length is supported by stone piers, the other half by timber piles. On ascending from it to the Munster Plaz, in which the cathedral stands, I was quite surprised to see the number of tall chimneys, each giving signs of fire below. I learned that Basle possesses many manufactories, and is particularly famous for her ribbons. Her manufacturers purchase raw silk in London, and send back their ribbons for sale there, thus beating the English manufacturers, though loaded with a double carriage. In 1846, the silk manufactures of Basle were estimated at 20,000,000 francs annually. The total value of the silk manufactures of Switzerland are about 35,000,000 francs. The Swiss have to compete with the French in this branch of manufactures. The superior education of the Swiss operatives gives them every chance of perfecting themselves afterwards. 'While the French workman,' writes Mr. Burnley, 'is lighter and nimbler, conceives and executes new things quicker, the Swiss is slower and heavier, but the more solid, steady, and reliable. The Swiss manufacturer has the advantage of a larger capital, and greater skill and practice in mercantile business.' The aptitude and energy of the Swiss for manufacturing is astonishing. We have long been familiar with the delicacy of the Geneva watches, which are mostly made by the peasantry of a particular district during the winter. But in textile fabrics the Swiss are beating both the English and the Belgians, each of which countries has, what Switzerland has not, a seaboard and large supplies of coal. The English and Belgians can receive the raw fibre, and export the manufactured article, at much less cost for carriage than the Swiss, who have no seaboard, and must receive their supplies either through Italy from Genoa, or through France. I understand the Swiss manufacturers content themselves with second-hand machinery, taken out of English mills to make room for more improved machines—that is, implements which will either do more work or do it better. These facts present a curious problem to political economists. Here is a country without coals, without seaports, and using inferior machines, beating two countries which possess all these advantages. Let us look at the cause, because nothing happens without one. What have the Swiss to compensate for these disadvantages? They have food grown by themselves, and they have water-power. As to food, England has to pay a large sum for it. This sum is partly the cost of the corn, partly the cost of carriage. The actual cost of wheat upon grounds of equal fertility is the same all over the world; it is only the seed and labour. If it be removed from Russia or America to England, then England must pay the carriage, and all the commissions or profits incident to collecting it from the farmers, in addition to the cost. Corn consumed where it is raised is, therefore, cheaper than it can be when imported. Switzerland has an almost unlimited supply of water-power. I think the river Aar alone would drive all the mills of Lancashire. It falls nearly 1,500 feet between Brienz and the sea, and the volume of water which pours along is surprising."

*The Foresters.**

GENERAL VIEW OF FORESTRY AND ITS WORKING.

We believe that it would be difficult to find in any other institution a wiser plan of government than is made manifest in the Order of Foresters. On the present occasion we must confine ourselves to the salient points of their regulations, but they will be amply sufficient to bear out the above opinion, and, we trust, to attract the attention of those whose special interest it is to support such an institution.

The first qualification for admission into the Order of Foresters is good health. Were it otherwise, the institution might become a mere hospital. No person is therefore admitted—excepting as an honorary member—who is in ill health. So much for the physical condition of the members; but morality is also required. No one is admitted—whether as an honorary or financial member—who bears a bad character,

* Continued from page 340.

who leads a dissolute life, frequents bad company, is guilty of habitual intoxication, or is of a quarrelsome behaviour. Any member knowingly proposing a candidate in opposition to this law is expelled the Order, or suffers such other punishment as the Court in which such misdemeanour occurs shall think proper. Should any member be convicted by a jury or by a magistrate of felony, larceny, or embezzlement, or by a committee of his Court of any crime or offence calculated to bring disgrace upon the Order, he is expelled, and his name is circulated in the quarterly report of the Executive Council. But such expulsion is not inserted until the time has expired for appealing to the Court next in superiority to that by which he is expelled. Of course, should the member ultimately succeed in establishing his innocence in any of the cases, after conviction, the law of expulsion and its consequences do not apply.

Nor is that all. The society wisely holds forth to her members the great boon of securing forgiveness and restoration by wooing the angel of repentance. Should any convicted member, on the expiration of the term of his imprisonment, show by his future good conduct, for the space of twelve months, a sincere repentance for his offence, and lead a sober, honest, virtuous life, he may, on application of the Court to which he formerly belonged, and with the consent of the Districts, be eligible for *re-admission*. It is only on being found guilty of a second offence that he is for ever expelled from the Order.

No person is admitted as a financial member who is under the age of eighteen years, or whose age exceeds forty years. With the Odd Fellows, the limit of age is thirty-six; but the Districts have discretionary power to admit persons above thirty-six years of age, upon payment of £1, and the contribution of the lodge for each lodge-night that has elapsed since the person admitted was thirty-six years of age up to the date of initiation, together with the additional payment, at the rate of 7s. 6d. per annum, in addition to the usual contributions during membership. We know not why a similar arrangement is not adopted by the Foresters, as it seems desirable to exclude no one from the benefits of such an institution. On the other hand, however, it must be in the power of very few working men to pay up such arrears.

The charges for initiation among the Foresters are as follows:—

	s.	d.
18 and not exceeding 25 years	5	0
25 „ „ 30 „	7	0
30 „ „ 35 „	10	0
35 „ „ 40 „	12	0

The regular contribution of members is 1s. 6d. or 1s. 7d. per month.

Any respectable person may become an honorary member, if of the age of twenty-one years, by paying 10s. 6d.; but he has no claim on the funds of the Court or Order, nor can he fill any office in the institution, excepting that of treasurer or trustee to a subordinate Court. Nevertheless, he has the privilege of expressing his opinions upon all questions brought before his Court, but he is not allowed to vote.

The Funeral Fund is provided in large Districts as follows:—To a District Meeting each Court sends a delegate, and the number of deaths that has occurred is taken into consideration. The number of members of each Court being returned by its officers to the District Meeting, a levy is laid in proportion, to be paid by each member, to cover the sum required for the purpose—hence the perfect ability to meet all demands on all occasions, or, in other words, the solvency of the Order. In the London United District of Foresters the fund is raised by the fixed contribution of 1s. from each member *per quarter*.

Every member contributing 1s. 6d. or 1s. 7d. to the various Sick and Funeral Funds, becomes thereby entitled to 10s. per week sick-pay for the first twelve months, after which he is reduced to half-pay. The funeral allowance is £10 for a member, and £5 for a member's wife.

Ample provision is made against the event of the breaking up of a Court or branch of the Order. In such a contingency, members, if not too old, are transferred into other Courts, without losing their benefits; and in the event of refusal consequent on advanced age, they are still provided for, by being placed on what is called the "High Court Fund"—to which every Court in the Order contributes its portion—to preserve, for this special purpose, a provision for the aged; and in the event of these High Court members falling sick or dying, the claims are paid by the High Court in the neighbourhood of such recipients. Isolation, or the standing alone, is the great drawback to those societies which have been so justly denounced. They have no branches, nor are they connected with any kindred societies whereby they could profit by example, or learn new methods of transacting their business, from the practical experience of others in different localities. They stand alone, or rather they are alone, and therefore cannot stand, besides being, by that very fact, open to much abuse in the management. True, the right-thinking men amongst them see things going wrong; but, being in a minority, they are unable to stay the progress of any wrong-doing; and if they persevere in their attempts at a reformation, every effort is made to remove the "disaffected" or "dissatisfied" member from the society, which is pretty generally effected.

Still worse happens in other cases, where if a member, through infirmity, has become burthensome, trumpery charges are brought against him, in order to frame excuses for the non-payment of sick-money, or for his expulsion. In either of these instances, the aggrieved member has seldom any remedy.

Not so with the Foresters. Here, if a member has not had justice done him, he has the power of appealing to what is called the "DISTRICT"—that is, a combination of Courts for the more effectual management of the business of the Order.

In order that the wishes and interests of every member of the Order may be duly represented, every financial Forester is entitled to vote in his own Court in the election of deputies to the High Court and District Meeting, as well as in the election of all its officers, and on other questions before the Court, excepting on the night of his initiation, or the night of throwing in his clearance, except such member is initiated on the opening of a new Court.

Every brother who has served in a subordinate office six months, and who is financial in his Court at the time of becoming a candidate, is eligible to occupy any office of honour in the Order—namely, the Chief Ranger of a Court, the officer of a District, or the Executive Council, with the same exceptions as before stated.

In order to preserve purity of election, and to prevent any improper influence or bias to induce a brother to give an unconscientious vote, it is determined that in the election of all officers of subordinate Courts, the vote shall be shielded by ballot, as likewise upon all other questions to be decided by vote, *if it be demanded by a brother*; but this is almost unknown, questions being decided by open vote. But open votes are always taken when the body consists of *deputed* members.

Here, indeed, is matter for meditation. A body of no less than *three hundred and one thousand men*, of what may be termed the *élite* of the working classes, united under one head, all actuated by the same principles of fraternal love, all endeavouring to outstrip each other in ameliorating the condition of their fellow-men, each having a voice in the introduction of some new feature, calculated to advance their social progress. It is, indeed, a grand example to set by so large a body of our fellow-countrymen. No greater bulwark could be imagined for the nation's peace and internal quietude than the fact that this large proportion of her male population is united for the universal dissemination of *unity, benevolence*, and *concord* amongst each other.

A striking instance occurred during the pressure of the Lancashire distress. At the High Court held at Portsmouth, £500 was voted to the Lancashire Relief Fund, for the aid of the Foresters suffering from the calamity; and subscriptions for the same purpose were made throughout the Order to the large amount of £3,000—all contributed by working men.

The solution of such a mighty problem is, indeed, a great fact in the modern advance of society. It proves what will result from unity of spirit and action, when adequately promoted by right appeals to the true self-interest of mankind. Such a society is a new apostolate for the elevation of the social state, to secure social well-being, to ensure peace and prosperity throughout the length and breadth of the land.

Facts and Memoranda.

THE COLONY OF VICTORIA.—In the year 1865, 30,976 persons arrived in the colony, and 25,292 persons quitted it; 25,811 children were born, and 10,466 persons died. The population increased 21,029 in the year, and at its close was estimated by the Registrar-General at 626,530.

UTILISING MARSHY LANDS.—Dr. Sacé has proposed a plan of utilising the marshes of France, which at present produce nothing but fever and ague. M. Sacé proposes sowing them with Canada rice, and turning down a lot of beavers; both the plant and the animal can live in any climate; both would be equally useful, and one would support the other. At present large sums are annually sent from France to America to purchase beaver-skins, which might thus become articles of home production.

WASTE OF COAL.—With regard to the total waste of coal in all the collieries of Great Britain by the destructive practice of burning at the pit's mouth great heaps of small coal and dust, it is not possible to present any precise or trustworthy information. There is too much reason for apprehension that it greatly exceeds what the public may suppose, or what the workers of collieries would be willing to admit. One illustration, on undeniable authority, shall suffice. The late Mr. Nicholas Wood asserted that, in 1861, the waste at the Hetton and Black Boy Collieries alone amounted to 160,000 tons of small coal in the year!—*Quarterly Review.*

NOVA SCOTIA MINES.—The Chief Commissioner of Mines has presented his report for the financial year ending the 30th of September, 1865. Royalty was paid in the year, upon 24,867 oz. of gold, an increase of 6,123 oz. over the previous year. About 700 miners were at work throughout the year upon an average; and calculating the gold at only 18 dol. 50c. per ounce, which is below its market value, the average yield per man was about 2 dols. 10c. per working day. The result of the coal mining of the year was also very satisfactory. The total quantity of round and slack coal sold from the mines amounted to 652,854 tons, an increase of 30 per cent. over the previous year. 59,536 tons were used for home consumption, 52,561 tons were exported to neighbouring colonies, and 540,757 tons to other countries, principally the United States. There are now thirty collieries at work in Nova Scotia. The iron mines are comparatively unimportant as yet, but about 1,500 tons of bar iron were shipped to England.

BRILLIANT MARBLED PAPERS.—In the factories where albumenised photographic paper is made a considerable quantity of paper is spoiled in the process, and it is then of but very little use. In Paris and Berlin this paper has always been washed as free as possible from the albumen, and then worked up into envelopes. Dr. Jacobson has found a new use for this paper; he proposes to stain it with aniline colours, and to employ it for labels, covers of boxes, and general decorative purposes. By being splashed with concentrated alcoholic solutions of the various aniline colours, the waste of these coloured papers, according to the *Reader*, is now converted into marbled paper, of a much more beautiful appearance than what is produced by the old process, from the green-gold lustre which the films of these substances possess. The papers obtained by this method retain the gloss, the bright "satin" surface of the albumenised material, and are almost as brilliant by transmitted as by reflected light. They are said to be well adapted for shades, transparencies, paper lamps, and other means of decorative illumination.

THE BUSINESS OF THE PATENT OFFICE.—A mistaken idea appears to be held by some people, who have, probably, little to do with novelties in engineering science, that the specifications are published shortly after the patent is completed; but they are only in so far published as the original documents are accessible at the Patent Office itself, and then only after paying a shilling for each patent specification it is wished to examine. We presume, therefore, that most readers will thus content themselves with the patent journals. The blue books are, in fact, some five months in arrear; but, as the Attorney-General has stated in the House, additional aid has been procured, which will probably bring up the arrears within a reasonable time. Of scarcely less value than the specifications themselves are the abstracts of the abridgments. The second parts of most of the older volumes are being prepared, amongst which is the long-delayed class for the manufacture of iron and steel. The fresh and additional classes being prepared are:—Preparation and combustion of fuel; steam engines; spinning; lace and other looped and netted fabrics; railways; railway signals and communicating apparatus; hydraulics; ventilation; raising, lowering, and weighing heavy bodies; rolling stock; acids, alkalies, oxides, and salts; agriculture; optical, mathematical, nautical, and astronomical instruments. Mr. Weild, of Manchester, is abridging the specifications relating to railways; Mr. Brierly those for spinning and lace; and Mr. MacGregor, of *Rob Roy* canoe celebrity, has been engaged for at least three years on those relating to steam-engines. Mr. MacGregor seems to be able to paddle his own canoe with greater speed than he can abridge specifications.

Political Intelligence.

The information communicated in this Journal relative to Mr. Clay's Intelligence Franchise Bill, has been the chief source of the public knowledge upon the question, so far as the press is concerned. Beyond what was said in Parliament, the chief elucidation of the subject has been furnished in the Working Man. Our correspondents who discussed the question did it in a manner which attracted the notice of the chief promoters of the Bill. As the question proceeds to obtain—as it will one day undoubtedly obtain—the approval of the public, it will be remembered as an historic curiosity, that in one paper alone the question was urged as useful to the working classes.

At the advent of the subject in Parliament, it has been mixed up with the party prejudices of the hour; and though the Bill was discussed an entire day, it was not discussed upon its merits, but used, on one side, as a means of frustrating another Bill before Parliament, and on the other side, it was dismissed with strong party condemnation. The intrinsic value of the principle had no attention; very little that was serious, and less that was true, was said about it.

We have concerned ourselves with the principle itself, and that alone. The first mode of bringing the principle into play, such as that adopted in the Elective Franchise Bill of Mr. Clay, may not be the best. It most likely will be, and we think is, open to amendment; but better modes can be devised, and will be devised, if the principle of intelligence as a test of political fitness be an inevitable one, as we think it will be, in the future stages of society. The old test of fitness for the franchise was power. Like property, those got it who were able, and those kept it who could. The men of landed interest were the arbiters of political power. When the franchise became extended to what were called householders, this was but a nominal variation of the landed interest, and only permitted so far as that interest could influence electoral results. But since population has increased, and landowners have decreased, and new commercial, factory, and mechanical interests have sprung up in the land, the old test has been changed, and floating property, apart from the land, has acquired power. There was a great outcry against it. No one was willing that peripatetic property, which might be here to-day and shipped to America or California to-morrow, should take a place of voting power equal to the fixed landholder. When the land line began to vary and vanish, a rental line was created, intended to represent quality and means. Now it transpires, in the great progress of the age, that rent does not represent mind, that patriotism lies deeper than rates, and that the highest qualities—those of intelligence and worth—exist among the common people as abundantly as among the uncommon; and the great experience of the cotton panic showed that the most needed qualities for self-government resided with the populace. The working classes of Lancashire acted well—not because they paid ten pounds of household rent, for they did not; nor because they paid certain rates, which they could not; nor because of any ancient way or principle of action among them, for their ways and principles were alike modern with the growth of modern times. They acted as Englishmen and patriots should act, because they were intelligent. The cheap press had made them men of sense. The intelligence of the people now rules. Public opinion, said the late Sir Robert Peel, governs; but public opinion is the average intelligence brought to bear on public affairs. To get at intelligence, then, is the true thing wanted. The worthiest men in the state oft remain poor. Honest industry does not always bring riches. Wealth is often impossible without crime. To make property the sole political qualification, is an error and an immorality. This base test is growing obsolete. A wiser, and fairer, and more popular principle is coming into notice—the principle of knowledge. Intelligence can be acquired without meanness, or personal slavery, or crime. Knowledge, Lord Bacon said, was power. It is not power yet, but it will be political power one day. It is a daily insult to honest poor men of sense to see the suffrage possessed by the most ignorant and unprincipled knaves in the land, if they happen to possess a little property, while no worth, or value, or service, or knowledge, counts for anything politically. At the hustings the ten-pound knave may be omnipotent, while the fit and honest man, falling below the line, is condemned to hoot his views, while his neighbour, without fitness or brains, can vote for his views. There is no doubt that all this will be amended one day, and the working man of intelligence be placed upon an equality with the well-to-do booby without it.

Electro-Plating.

The manufacture of electro-plate is a branch of industry demanding a special description. We have no details of this manufacture as carried on in England, but we have particulars of the Christofle Company's works at Carlsruhe, which are of first-rate importance, seeing that the total number of persons employed amounts to 1,432, involving an annual expense of £250,000.*

The metal employed in this manufacture is called *maillechort*, being derived from the names of the two workmen of Lyons, *Maillot* and *Charlier*, who recently invented this alloy, which closely resembles silver, having the same colour and "ring." In Germany it is called *argentan*, in England, *British silver*.

Maillechort is a compound of copper, zinc, and nickel—the nickel being added to render the alloy whiter and harder. The proportions of the metals are, ordinarily, in 100 lb.—copper, 55; nickel, 23; zinc, 17; iron, 3; tin, 2 parts. For inferior articles the proportion of nickel is as

* "Les Grandes Usines; Etudes Industrielles en France et à l'Etranger." Par Turgan.

small as 4 per cent.: *alfenide* contains 12 per cent.

The alloy is melted in crucibles, in quantities of half a hundred weight at a time. Two blast-furnaces working in conjunction produce a ton of flat ingots a day. These ingots are smoothed in a planing machine, specially contrived for the purpose, the knife of which is of the same width as the ingot, and, by a single movement, removes the rough surface: a workman can make 100 ingots a day. After planing, the ingots are put between powerful rollers, which extends them to five feet in length, and brings them to the desired thickness.

During the interval of the different operations, the ingots are heated several times, to restore their original elasticity. This operation is performed in a reverberatory furnace. After each heating the metal strips are cleaned by the usual methods.

Take, as an example, the manufacture of a spoon: the strips are placed under an eccentric cutter, which cuts the *blanks* which are to take the form of a spoon. The blank is of the same thickness throughout. It is necessary to vary this thickness, and at the same time lengthen it and shape the spoon. This result is arrived at by means of a steel roller, upon which the various shapes are cut.

These rollers are mounted upon the frame of the rolling-machine, with a fly-wheel, and produce six articles a minute.

The bowl now undergoes a first pressure for breadth. The handle undergoes a rolling for length and breadth, both at the same time.

The three portions are next extended to the exact dimensions of the finished article; it then only remains to give the last touches, which is called "finishing." This is performed on a machine having the form of the roller, but only making a "to and fro" motion, by means of an eccentric. The object of this machine is to effect a more uniform pressure, by lengthening the material more equally, without producing undulations.

In this machine the matrices, instead of being engraved rollers, are segments of steel mounted in blocks of cast iron, the pressure being regulated by means of screws. Two workmen are required for this operation: one places the articles, the other receives them and guides their delivery. This form of machine has been adopted, because in the rollers we cannot go on increasing in width indefinitely, on account of the cost of large rollers, while in the segment machine the surface to be worked is upon a circumference 24 inches in diameter. A pair of cast-steel rollers, $4\frac{3}{4}$ inches in diameter, are worth £15; when engraved, more than £20.

The greater the diameter of the cylinder the more regularly the rolling is effected, for the pressure takes place normally, on the surface; if this surface approaches a straight line, there will always be more chance of preserving the accuracy of the article submitted to pressure. The quality of the products resembles those furnished by the balance-lever, which are excellent. The balance-lever can scarcely turn out an article a minute; the segment machine produces eight during the same space of time. Besides, the pressure of the segment machine is never exercised except upon one point, and thus a smaller force will produce the same effect as a machine which, like the coining-press, impresses the whole surface of the article at once.

A single machine of this kind can easily furnish 150 articles a day, including the time necessarily lost in mounting and putting the machine in motion.

On leaving the machine the article is flat. To remove the roughness produced in the press, it is presented to a coarse emery-wheel, turning vertically, and the dressing proceeds rapidly. The operation is completed on a finer emery-wheel.

The spoon is next placed between matrices in the centre of a balance-lever; forks are cut under a lever cutter. The bend in the shape of each is given by means of a machine with two levers upon a cast-iron matrix containing the shape.

The flat portions of the spoon are now regulated by filers, who also work upon the teeth of the forks. This work is performed in a vice with wooden jaws, adapted for different shapes. The article is now ready to be polished.

PROCESS OF HAMMERING.

Polishing is performed on wheels moving with a velocity of 2,000 revolutions a minute. Pieces of buff, cut into different forms, are mounted on the axle of the wheel, and by means of rottenstone and oil, the marks of the file and the asperities on the surface are removed. A brush of bear's bristles completes the work, by rendering it perfectly smooth.

Between each operation the articles are conveyed to an office, counted, and verified, and all that have the slightest defect are withdrawn; the most trifling irregularity—a flaw, or black spots where the material is deficient—condemns the article.

It requires 6 lb. of metal to be melted and rolled in order to produce 2 lb. of articles fit to sell.

Many articles are shaped simply with the hammer. Their ornamentation is produced by the method known as *repoussé*—punched or chased work—by means of which arabesques, flowers, &c., are obtained, chiselled in relief upon the brass by the aid of a bar of elastic steel, one end of which is held by a vice, while the other end, slightly curved like a claw, is furnished with a round, polished point. This steel bar, placed upon the vase to be ornamented, receives a "to-and-fro" motion from blows with a hammer, so that its polished and curved end strikes in the desired spot and forms a depression or hollow. By a suitable rotary movement, the ornaments, in this manner, are executed with great perfection.

The number of articles annually produced by the Christofle Company is enormous, amounting to 80,000 dozen, distributed as follows:—300,000 dish-covers, 35,000 dessert articles, 550,000 coffee spoons, 90,000 table and dessert knives, and spoons of various kinds, consuming 8,500 lb. of silver. The establishment is paternally administered. The company looks to the future welfare of the workmen, and creates an important fund for their benefit, besides maintaining a number of beds for invalids at Vincennes and Vésinet. A workman who remains uninterruptedly ten years in the employment of the company receives a present of 500 francs in a credit on the savings bank: 150 francs for the first five years, three years more gives another 150, and two years more 200.

INVENTION OF THE STOCKING-FRAME.

The accounts which have been preserved of the circumstances connected with the invention of the stocking-frame are very confused, and in many respects contradictory, though there is no doubt as to the name of the inventor. This was William Lee, born at Woodborough, a village about seven miles from Nottingham, about the year 1563. According to some accounts he was the heir to a small freehold, while according to others he was a poor scholar, and had to struggle with poverty from his earliest years. He entered as a sizar at Christ's College, Cambridge, in May, 1579, and subsequently removed to St. John's, taking his degree of B.A. in 1582–3. It is believed that he commenced M.A. in 1586; but on this point there appears to be some confusion in the records of the University. The statement usually made, that he was expelled for marrying contrary to the statutes, is incorrect, as he was never a Fellow of the University, and therefore could not be prejudiced by taking such a step. At the time when Lee invented the stocking-frame he was officiating as curate of Calverton, near Nottingham; and it is alleged by some writers that the invention had its origin in disappointed affection. The young curate is said to have fallen deeply in love with a young lady of the village, who failed to reciprocate his affections; and, when he visited her, she was accustomed to pay much more attention to the process of knitting stockings and instructing pupils in the art than to the addresses of her admirer. This slight is said to have created in his mind such an aversion to knitting by hand, that he formed the determination to invent a machine that should supersede it, and render it a gainless employment. For three years he devoted himself to the prosecution of the invention, sacrificing everything to his new idea. As the prospect of success opened before him, he abandoned his curacy, and devoted himself to the art of stocking-making by machinery. . . . . Whatever may be the actual facts as to the origin of the invention of the stocking-loom, there can be no doubt as to the extraordinary mechanical genius displayed by its inventor. That a clergyman living in a remote village, whose life had for the most part been spent with books, should contrive a machine of such delicate and complicated movements, and at once advance the art of knit-

ting from the tedious process of linking threads in a chain of loops by three skewers in the fingers of a woman, to the beautiful and rapid process of weaving by the stocking-frame, was indeed an astonishing achievement, which may be pronounced almost unequalled in the history of mechanical invention.—*Self-Help: New Edition.*

On the Introduction of Beer into Working Men's Clubs.

BY THE REV. H. SOLLY.

As this subject is attracting increasing attention, it may be well to offer a few remarks on the subject in the columns of the Working Man, considering it, as I do, to be one of vital importance.

I mentioned, in a former number, that the question was pressed upon the notice of the recent Conference at West Bromwich by every one of the delegates then present, all of them advocating its introduction, under due safeguards, and being supported strongly in their views by Mr. Jones, secretary of the South Staffordshire Adult Education Society; and in reply to the arguments which I then used, in opposition to those views, the delegates replied, that if the men were relieved from the pressure of the landlord, and could drink beer unadulterated with drugs or salt, there would be no danger of excess beyond what the committee and steward could easily control. That, in short, if the men could have their own public-houses on the Co-operative principle, the present ruinous and demoralising system would be completely put an end to. The question is coming on again for discussion at the next quarterly meeting, to be held in Oldbury, and I would, therefore, invite the attention of the members of the South Staffordshire Clubs especially, and of clubs throughout the kingdom generally, to the following suggestion.

It was quite admitted at the West Bromwich meeting that constant supervision—nay, vigilant superintendence—would be required, to prevent any mischief resulting from the sale of beer in Working Men's Clubs—at all events, in that part of the country. But it was considered, that if two members of the committee were always present of an evening, and if the steward or housekeeper could be relied on, no harm would result. In reply to my question, it was stated, that should a man in a doubtful condition apply at the bar of the club for a pint of beer, the person in charge might refuse to supply him until a member of the committee had been consulted.

Now, all this (and much more might be said to the same effect) clearly indicates a conviction in the minds of the advocates for the introduction of beer that, to say the least, there would be serious dangers attendant on it. Every one acquainted with working men knows that, at the present time, one of their chief dangers and temptations to excess arises from the habit of "standing treat." This temptation would still exist, though the desire of pleasing the landlord were removed. The club and its members, in fact, would be sitting on a powder magazine, which a spark might at any time explode; because, even if the men in the club were not in danger of drinking to excess when the pressure of the landlord was removed, a man might at any time come in who had been drinking freely elsewhere of a less innocent mixture, and a pint that he got at the club, evading the vigilance of the steward, might be quite sufficient to finish him.

At one of the conferences held last autumn, Archdeacon Utterton, of Farnham, who has been instrumental in establishing a very large and successful club there, mentioned this difficulty, saying that, though he had desired to see beer introduced, thinking it the best chance for competing with the public-house, he had never seen his way to its safe admission; because, if it were sold at the club, men who have come in after they had had plenty elsewhere, might get completely upset by what they had there, and the club would bear the blame. Archdeacon Jacobs, at the same meeting, quite agreed that it was of the utmost importance to help working men to break the habit of tippling, and that he was quite convinced of the policy of excluding beer, adding with great force: "If we get the higher class of working men we shall gradually win over the lower; but I believe now we shall not get the higher sort if we introduce beer."

This goes very much to the root of the matter, because those working men who are most anxious to benefit their class, and who now continually make sacrifices for that purpose, are well aware that all their efforts are useless unless they can change the habits of their mates with regard to drinking.

I have constantly found gentlemen advocating the introduction of beer into clubs, but as constantly have found the working men themselves object to it. It was two clergymen, at this very conference before mentioned, who raised the discussion by asking if we did not think that beer should be introduced.

Let me here quote what I urged on the subject in a letter addressed to our friends at Leicester some time since:—

Clearly then, having regard to existing habits among working men, these men feel that, *under present circumstances*, the clubs would not prosper—would, in fact, become little better than beershops—if the rule in question were not enforced. But they feel and urge this, mark, not because the working classes as a rule are drunkards, or that the majority even are in the habit of frequent excess. To say that would be to libel the most industrious workers under the sun. No; but because those workers have so frequently the habit of drinking between meals—tippling, in short, when they are talking, smoking, and playing, especially of "standing treat," first one and then another, all round—in consequence of having had no place but the public-house for social intercourse and recreation. Now, the thoughtful working men who come forward to establish or join the clubs know that this habit must be broken if they are to make any progress, individually or as a class. Many years ago, as I believe I mentioned at the public meeting in Leicester, a hard-working journeyman blacksmith (not a teetotaler) said to me as we came out of a temperance meeting, "Ah, Mr. Solly, what you've got to do is to get us to give up the public-house. It's not what we get at home that would hurt us; *it's what we drink when we get together.*" Or, as another working man said recently, and as working men have said to me many a time in all parts of the kingdom, "It's the *company* that does it."

Few persons could live a month among the working classes of this country without perceiving that in this club movement we have to deal with an exceptional state of things, and that a rule is unquestionably needed in their clubs, at present, which in all probability will be no more required ten or twenty years hence, than it is now at the "Reform" or the "Carlton." But if any impartial judge still doubts the expediency of "prohibition," or the existence of the habit of tippling *when the beer is to be had*, let him reflect on the efforts now being made not only by official authority, clergymen, magistrates, and others, but by the working men themselves, in large numbers, to get the meetings of their Friendly Societies held away from the public-house. True, there would not always at first be the same inducements at a club to drink "for the good of the house;" but wherever beer was allowed, there would soon be offers to farm the refreshment department at a rate that would be very tempting to committees, often puzzled to make both ends meet; then, when once that was done, the sale would soon be pushed, and the pot-boy's well-known cry would be heard through the club rooms, "Any orders, gentlemen? give your orders, gen'l'men, if *you* please!" If that were resisted, the silent presence of the steward, or an occasional visit from him, with a slightly demonstrative gathering up and clinking of the empty pewter pots, would generally be quite sufficient. To restrict the consumption of each member, say to one pint, would be felt to be a far greater stigma by the men than to exclude it altogether, *except* in a dining-room.

I can quite believe that, in many places, if it were known that beer could be now had at the Working Men's Club, considerable numbers of men might join it who at present stand aloof, preferring the publican's fire-side and beer to the coffee-room of the club; but the question is, Would the real usefulness and ultimate existence of the club be thereby promoted? I cannot believe it, for it would be sacrificing the permanent good of these societies to mere temporary gain in point of funds and numbers, while their whole character and objects would be seriously injured; and, as it so often happens, for the sake of present apparent advantage the real worth of the enterprise would be to a great extent destroyed. I doubt very much if the men who would come merely because they could have beer would be likely to add anything to the general good of the institute, while they would be in constant danger of woefully interfering with its usefulness, and lowering its character.

If the clubs are to be of any use at all, it will surely be by helping to raise the tastes and refine the habits of working men, and by supplying them with better amusements and excitement than they have hitherto been dependent upon; and I believe that the present generation of gentlemen little know the extent to which many a respectable working man longs now to get out of the atmosphere and temptations of the beery customs so long prevalent among them. On this point let me again quote:—

But even if this danger (pushing the sale) could be averted, the fatal objection still remains: "It's the company that does it." No doubt there are thousands of working men who, as I said above, do not now come to the clubs, because they have been so accustomed to drink beer in their hours of relaxation, that they are not comfortable anywhere without it. They, of course, would vote for its introduction into clubs, unless they had resolved to break themselves of a habit which they felt to be wasteful and mischievous. But other thousands who now support the clubs, and object to the beer, do so either because they say, "We must help ourselves and (or) our mates to break that habit, and we can't do this as long as the beer is to be had;" or because they feel that they must protect themselves in the quiet and orderly enjoyment of the club, which would be sooner or later interfered with, if the men who can't enjoy themselves without beer were to come and drink at it. These men say, "When we want a glass of ale, we know where we can get it, and we prefer having it before or after we are at the club, or even going out and coming in again, to letting it be on the premises, where we could get it just when we wish—which, in the case of many of us, would be during a great part of the evening." Some, in short, want the club as a refuge for themselves, some for their companions, and in either case don't wish to have their social intercourse and recreation any longer marred by what they well know is the worst foe to the social elevation of their order and the well-being of their homes—viz., a habit which has to so great an extent been engendered by outward circumstances, and which, therefore, *by a change in those circumstances*, may, to a great extent, be eradicated.

Now, my dear sir, allow me earnestly to ask, Ought not those men, who are in no danger of taking "a drop too much," to have some consideration for the large number of their companions who *do* feel the tremendous force of habit and custom? Would it not be more *brotherly* to say they will get their pint as they pass "the public" *before* they come to the club, or at home, instead of insisting on having it where it would very likely lead other men to have a gallon? I take it for granted these steady men have a desire to see their class raised in the social scale, and that they join the club not merely to get a little good out of it for themselves, but also because they believe the club will improve the position and character of the working classes generally. But if they merely get their mates to drink in one place instead of another, I fancy they will not be doing them much good. The wives of the drinking men, at all events, would very soon be inclined to say, "Well, we heard this club was going to do such a deal for our masters, but we don't find much difference on Saturday nights."

PALISSY'S LAST DESPERATE EXPERIMENT.

His money was all spent, but he could borrow. His character was still good, though his wife and the neighbours thought him foolishly wasting his means in futile experiments. Nevertheless, he borrowed sufficient from a friend to enable him to buy more fuel and more pots, and he was again ready for a further experiment. The pots were covered with the new compound, placed in the furnace, and the fire was again lit. It was the last and most desperate experiment of the whole. The fire blazed up; the heat became intense; but still the enamel did not melt. The fuel began to run short! How to keep up the fire? There were the garden palings: these would burn. They must be sacrificed rather than the great experiment should fail. The garden palings were pulled up and cast into the furnace. They were burnt in vain! The enamel had not yet melted. Ten minutes' more heat might do it. Fuel must be had at whatever cost. There remained the household furniture and shelving. A crashing noise was heard in the house; and amidst the screams of his wife and children, who now feared Palissy's reason was giving way, the tables were seized, broken up, and heaved into the furnace. The enamel had not melted yet! There remained the shelving. Another noise of the wrenching of timber was heard within the house, and the shelves were torn down and hurled after the furniture into the fire. Wife and children then rushed from the house, and went frantically through the town, calling out that poor Palissy had gone mad, and was breaking up his very furniture for firewood! For an entire month his shirt had not been off his back, and he was utterly worn out—wasted with toil, anxiety, watching, and want of food. He was in debt, and seemed on the verge of ruin. But he had at length mastered the secret, for the last great burst of heat had melted the enamel. The common brown household jars, when taken out of the furnace after it had become cool, were found covered with a white glaze! For this he could endure reproach, contumely, and scorn, and wait patiently for the opportunity of putting his discovery into practice as better days came round.—*Self-Help: New Edition.*

*Co-operation among the Fisher-Folk.**

THE SCOTTISH FISHERMEN.

The importance of the position achieved by the dredgers of Whitstable will be best shown by what has not been done, but might have been done, by the oystermen of Newhaven, near Edinburgh. In the Firth of Forth there are several extensive and valuable oyster-beds, which are held from various owners, at an almost nominal rent, by certain of the fishermen who are members of a friendly society; but instead of these beds being held and worked on the co-operative principle for the general good of the members of the society in question, they are worked on the competitive plan of each man dredging for his own hand; and it is notorious that, in consequence of this way of working, these beds have been greatly abused by the abstraction of both brood and immature oysters, which have been sold at a cheap rate to the proprietors of private oyster-beds both in Holland and England. Had the Newhaven men cultivated oysters on a systematic plan, they might, from the low rent which they pay for the scalps, and from the facilities of rapid transit, coupled with the high price now obtained for oysters, have easily acquired wealth and independence. As it is, they have, we fear, lost their chance, for the Corporation of Edinburgh, to whom a portion of the Firth of Forth scalps belong, are so anneyed at the reckless and indiscriminate way the beds have been dredged, that they will not likely renew the lease, nor, in all probability, will the noblemen and gentlemen who are the owners of the remainder of the oyster-ground be induced to continue as tenants persons who are so careless of the future of the most valuable natural oyster-beds in the kingdom. Even at the present time a paragraph is going the round of the local papers to the effect that the small oysters, instead of being thrown back into the sea in order that they may grow large enough for the market, are being sold to be deposited in English feeding-beds at the rate of 9s. or 10s. per thousand. When will these fishermen learn common sense? If this course of conduct is continued, the people of Edinburgh will very soon have to buy their oysters from the capital of Maryland, in America!

The fishermen of Newhaven (on the Firth of Forth) are all men of excellent character, sober and industrious. A little time since they were engaged in what is called the winter herring fishery, and during the short season it lasted their efforts proved very successful. All have done well, and one or two of the men, it is said, have realised a considerable sum of money. Some boats took fish (herring) to the value of £40 every day, and one boat at the termination of the fishing had £400 to divide among its crew.

Many of the fishing-people of Scotland join together in the prosecution of the fisheries. It used to be at one time the rule in the Scottish fisheries for all employed to share in the work, and in the profit as well—indeed, at many of the smaller fishing villages it is still the custom for some of the poorer families to join in fitting out a boat; and there have been instances where the one boat, by prudence, industry, and good management, has served as the nucleus of a fleet. A boat and its appurtenances, such as a large drift of herring-nets (unfortunately, it takes a very long drift of nets now-a-days to catch a large quantity of herrings), and the necessary deep sea-fishing gear, costs, comparatively speaking, a great deal of money, say from £100 to £200, which is a large sum for poor fisher-people to accumulate. Yet there are families in the fishing villages who are really wealthy, the possessors of, perhaps, half-a-dozen boats, with the corresponding gear of nets, lines, sails, hooks, dredges, spare masts, &c.

The Whitstable system, described in our former paper, of carrying on business for the joint account of the whole community, is an admirable one; it is better than the system now largely prevalent in Scotland of the boat-master contracting to fish for the curer; this plan is always adopted during the herring season, and also by many of the fishermen for the disposal of their deep-sea white fish. The curer employs so many boats to fish for him, paying their proprietors so much for a certain quantity of haddocks, or herrings, as the case may be, he providing all the etceteras for the proper cure of the fish, or sending them to market fresh, if that be his way of doing business. The bargains made between the fisherman and the curer are worthy of being noticed. As regards the herring fishery, the curer usually contracts that each boat shall deliver to his cooper, or other servant, 200 crans of green—that is, fresh fish (herrings). A cran being forty-five gallons of ungutted fish, our readers will easily form a notion of the quantity; but to keep them right it may be assumed that a cran will contain say 800 ungutted herrings. Each boat proprietor, therefore, bargains to supply the curer with 160,000 fish, and, as a curer may have from fifty to 200 boats fishing for him in the course of a season—the late Mr. Methuen would have far more than the latter number—our readers will see what an enormous quantity of herrings is yearly caught on the British coasts. The bargain between the curer and the fisherman is always fixed at so much per cran. Let us suppose the sum to be 15s. per cran, then "a bounty" is always included: let us fix this, to be moderate, at £15 per boat; then a certain quantity of whisky has to be provided by the curer as well; also ground on which to dry the nets belonging to each boat he engages likewise dye-stuff, locally called *cutch* (catechu), with which to "bark" nets and sails, so as to prevent their being rotted by their alternate exposure to sun and sea. It will thus be seen that the curer has to pay a total sum of about £180 for his 200 crans of herring and the furnishings just mentioned; it is wonderful, therefore, when we take this sum into account, and add the charge for inland carriage, that herrings can be obtained so very cheap as we now find them to be. A change in the mode of doing business during the herring season is very much wanted. There is no certainty that any one boat will take 200 crans of fish during the season; indeed, the average per boat at Wick for some seasons back does not show 100 crans. Of course, the curer pays for no mere herrings than he obtains, but still the bounty money is faithfully exacted; indeed, it is always paid down at the time the bargain is made, which is generally about the conclusion of the current season. The commercial system which has been engrafted on the herring fishery is, to speak plainly, just a mode of gambling. Curers are, many of them, more or less dependent on buyers; buyers, again, hang on the skirts of one or other of the great foreign merchants—Austrian or Prussian; these apply to their bankers, and so the springs of herring commerce are moved, there being a binding together of the various interests in the way depicted. And, again, any ambitious fisherman can, by going to a curer, obtain the means of starting a boat; the curer will, of course, bind the fisherman to fish for him, obtaining for himself some little advantage in making the bargain, besides good interest for the money lent. The fishermen who thus hasten, as they think, to be rich, seldom do so well as those who work their way up to be proprietors by economy and industry. Three lads will, perhaps, club their savings, and so obtain a boat and part of the necessary gear, which they will go on adding to from time to time, as their "luck"—that is, success—will admit. They, of course, act as their own crew, obtaining the assistance of a couple of hired men during the herring season. The boat being their own, if they are lucky and make a good catch, they will do well, having so little outlay for labour, and in good time they will acquire another boat, and so grow in prosperity. One thing we would suggest to the fisher class, and that is the forming of an insurance fund. It is pitiful, wondrous pitiful, to know of the want and misery that is sometimes involved by some of the great storms that sweep the north-east coasts of Scotland. In a few hours, so sudden are the changes of weather, a dozen of mothers will be made widows, and fifty children will be fatherless. Were the boats and gear insured even for half of their value, it would provide a little fund which would, for a time at any rate, yield a sustenance to the widow and the fatherless.

On these calamitous occasions the fisher-folk are very kind to each other, and we have more than once known a family of bereaved little ones settled out in a fishing community, the most active persons in affording succour being those, perhaps, who had a great enough struggle for the maintenance of their own family; but, as a rule, the peer are always kind to the peer. Many of the Scottish fishermen are, we are happy to say, in very good circumstances, and possessed of what in their station may be esteemed great wealth. Some of the boat-owners also follow a trade, many of them being masons, carpenters, tailors, or small farmers; these only go out in the herring season, when more or less money is sure to be made. The herring season lasts only for a few weeks, but it is a period of great activity; and when we state that no less than 1,000 boats will fish from the little port of Wick for herrings during the present season, the readers of the Working Man will be able to form a judgment of how great must be the total "harvest of the sea."

* Continued from page 331.

CONVERSION OF CAST IRON INTO CAST STEEL.

A new process, for the rapid conversion of a mass of cast iron into cast steel, homogeneous and of great purity, has been thus described by M. Galy-Cazalat, in a memoir addressed to the Academy of Sciences:—"Cast steel is a combination of iron with some thousandth parts of carbon, and cast iron consists of iron and about five per cent. of carbon, alloyed with silicium, sulphur, and other metalloids. Hence, it results that steel may be obtained by causing currents of gas containing oxygen, and particularly superheated steam, to pass through a mass of cast iron in fusion. In traversing the mass of molten metal, the steam is decomposed; its oxygen burns the carbon and oxidises the iron, while its hydrogen takes up from the metal its sulphur, phosphorus, and other metalloids, which would render the steel brittle. In proportion as the cast iron loses its carbon, its temperature rises rapidly beyond the melting point of the steel. When the colour of the flames, which rise from all parts of the surface, indicates a suitable degree of decarburation, the steel is then run into the mould. This system, the most simple and least costly, of fabricating steel in large masses, was conceived by M. Galy-Cazalat, and experimented upon at the Palais de l'Industrie, during the Universal Exhibition of 1855. Since that period he has operated on a large scale, both in a crucible containing five tons of cast iron, and in a reverberatory furnace, of improved construction, the flame of which produces the steam necessary for the decarburation. Unfortunately, the characteristic indicative of the precise transformation of the cast iron into steel being uncertain, we obtain sometimes pure iron without carbon, and at other times an alloy of oxide of iron and too much carburetted steel, according as we allow too much or too little steam to pass through. This inconvenience was common to my process and that of Bessemer, who, in 1856, took out a patent for making steel, by causing to pass through the cast iron, in fusion, currents of air compressed at heavy expense by machines thirty times more costly than the reverberatory furnace, which produces the steam. Lastly, for the last three years, the inconvenience arising from the uncertainty as to the number of minutes after which the decarburating currents of air, steam—or, rather, oxygen—must be stopped, has no longer existed; the manufacture is regular, and we obtain always common steel by decarburating completely the mass of melted cast iron, either by air or by steam, and then adding 10 per cent. of spathic iron ore, to restore to the iron the carbon required to form steel. This steel, now used for railway bars, requires, however, to be re-cast so as to become homogeneous and of superior quality, and this second operation, which is carried on in crucibles containing 44 lb., doubles, at least, the cost of homogeneous cast steel." In reflecting upon the chemical reactions which take place in the crucibles, the author of the memoir perceived that for these reactions to be brought into play it is requisite and sufficient that common or heterogeneous steel be maintained, during at least fifteen minutes, in quiet fusion, and at a temperature of about 2,700 deg.; the metallic mass then becomes homogeneous, and its particles acquire a regular aggregation. Under these two conditions the oxygen abandons the oxide of iron to combine with the free carbon in the steel, whence it is disengaged either in the state of carbonic oxide or carbonic acid gas. The reverberatory furnace has been perfected, so as to be able to arrest the currents of decarburating gas, without their discharging orifices being obstructed by the liquid metal getting into them. It suffices, then, to shut the cock which lets the superheated steam into the bath, the mass of which is no longer agitated, and to open another cock, which sends a jet of steam into the chimney, so as to quicken the combustion on the grate of the furnace, which speedily reaches a very high temperature. We are aware that pieces of steel cast in moulds are full of cavities, which considerably weaken their tenacity. In order to give to the metal all its resistance, it is generally, after having been suitably heated, submitted to the pressure of a roller, or to blows of a steam hammer, which cause the particles of the metal to adhere closely, and the bubbles to disappear. The rolling and hammering being very costly, and often impracticable—as, for instance, in the case of steel cannon with trunnions

and handles—M. Galy-Cazalat has contrived to make these cavities disappear by submitting heavy guns to great pressures produced by gases, while the metal is still in a fluid state, in the moulds of sand, firmly bound by strong frames of iron of suitable resistance. For this purpose, immediately after the casting of the complete cannon, the whole is covered hermetically by a metallic cap, screwed firmly to the framework of the mould. This cap carries a vertical tube, furnished with a cock at the lower extremity, and closed at the top by a less-resisting membrane, or safety diaphragm. It contains six to ten grammes of powder, without sulphur, composed of eighty parts of saltpetre and twenty parts of charcoal. When the cock is opened the powder falls upon the metal, is ignited, and the combustion produces rapidly ten litres of gas for each gramme of the mixture of saltpetre and charcoal. The imprisoned gases under the cap exert on the surface of the liquid steel a pressure which is transmitted simultaneously and regularly through the entire mass of the cannon, effectually effacing the bubbles, and increasing the tenacity of the metal, which is the same throughout.

Mechanical Construction of the Houses of Parliament.

We do not propose to give any account of the political construction of the Houses of Commons and Lords, which, indeed, involves a curious system of architecture. We speak of the actual mechanical construction of the buildings, which has more direct interest for craftsmen. A paper was lately presented to Parliament, and published by it, from the pen of Dr. Percy, who has charge of the ventilation of the Houses of Commons and Lords, in which the doctor states some unexpected facts. The public are aware that that costly house—or, rather, houses—were built of friable stone. What could Sir Charles Barry be thinking of, to erect such an elaborate and ornate building of a material that would decay before Sir Charles himself died? Was it not a strange waste of public money to expend a quarter of a million upon a structure that would crumble in a generation? Was nothing known of the qualities of stone? Could not the architect tell one from the other? Did he not know which was which? If we select tried men for a public office which must terminate in a few years, should not an architect select a tried stone?

Even this inexplicable proceeding seems surpassed by a fact told by Dr. Percy. The Houses of Parliament are ventilated and warmed by pipes. There are fifteen miles of steam-pipes about the building; there are many hundreds of air-courses, under as well as above ground, beneath floors, in walls, over ceilings, and in roofs: some for supplying cold air, others for supplying warm air, and others again for carrying off vitiated air; there are air-valves in every part of the building; there are enormous smoke-flues running horizontally within and immediately under the roofs, with hundreds of chimneys in communication; there are 1,200 stop-cocks and valves, connected with the pipes; and there are a multitude of holes and crannies, as intricate and tortuous as the winding of a rabbit warren: and the astonishing thing is, that no plan of these pipes, flues, channels, and crannies was ever made. All this enormous expense was gone to, and this incredible network of iron was laid about, up and down, and not a note was made of the windings of this maze of currents and flues. He is a well-informed man who can make his way about the Houses and not lose himself; but who shall be able ever to follow these pipes and stop-cocks about? What man could hope to remember accurately all the details, even had he seen every stone and brick laid? It would need a professor of artificial memory to get all these facts by heart, and he would need to have some hereditary order of assistants, born with a knowledge of these particulars, or capable of acquiring them. We need not say that no such persons exist; and in the absence of plans, all sorts of blundering occurs. The First Commissioner, on being made aware of the state of the case, took steps to remedy the evil, and for several months an architectural draughtsman has been engaged for the purpose of preparing the necessary drawings of these concealed and subterraneous works. Aided by two of the most experienced men of the Parliament House staff, the laborious and difficult explorations have been going on for a long time, and are likely to continue. In many cases it has not been found possible to trace the course of these air-passages. At the end next Westminster bridge stands the Speaker's house. All the air-courses in the west front of Mr. Denison's residence, and in the river front, have been thus explored, described, and catalogued, and plans of them are in progress. In the course of these explorations, it was found that some of the fresh air supplied to the Speaker's house "passed over two urinals." This is an uncomfortable fact to publish, but Dr. Percy gives it in a note. It is necessary that some of the mysteries of ventilation should be known.

Obviously, a considerable time must elapse before all these explorations can be completed. Floors have to be raised, ceilings disturbed, walls broken into, and all sorts of excavations effected, before the truth can be known. Much has been discovered of which no one knew anything. Duplicate descriptions of all discoveries made, and of all tracings effected, are deposited at the Office of Works, where they will be securely preserved for future guidance. It is plain that, without accurate plans, this department of ventilation and warming must be at the mercy of the persons employed, and supposing any one of them possessed an accurate knowledge of the subject, which no one does, it would never do to trust to his memory alone.

There are many curious facts beyond these noticed, which we may find other occasions to enumerate. But we will not refrain mentioning now some of the freaks of effluvia, which may be instructive. Unless the courts and sides of these great Houses are kept perfectly sweet and clean, the fact becomes unpleasantly palpable in the building. If horse-dung happens to fall near any of the inlets to the House, the air entering becomes affected. The Commons' court, where carriages wait near the entrance to the Ladies' Gallery, is close to the inlet of air on that side to the House, and the presence of horses is often felt in the House. If a person while smoking merely walks through the Commons' court, in a few seconds of time a distinct odour of tobacco-smoke will be perceived, especially near the Speaker's chair. If a person smoke near the Members' entrance to the House, the odour makes its way up-stairs into the lobbies. When the kitchen windows of the House are open, and cooking is going on, the Members in the House find the flavour of dinners mixed up with their debates.

As the effect of gas works is just now in dispute, we may notice a remark occurring in Dr. Percy's instructive and well-written report. It is this. The smell of gas tar was several times perceived during last session in the House of Commons, and elsewhere in the Houses of Parliament, and on investigation it was found that the tar from the Chartered Gas Company was transferred from carts through open gutters into barges moored just under the south wall. "A representation of the subject was made to the directors of the company, and they promised immediately to abate the nuisance." "Nuisance" is Dr. Percy's word.

THERE'S MORE THAN LUCK IN THE SAVINGS BANK.

At a recent meeting in the Pottery districts, Mr. Baker said—"Many working men had their own houses, and many more might have had them had they been so disposed. Some years ago he took considerable pains to indoctrinate the Yorkshire operatives, amongst whom he moved, with the idea that any man might, by practising frugality, between the ages of eighteen and thirty-two, become the possessor of a freehold, and that by merely putting into a savings bank 3s. 6d. per week. On one occasion he was going through a large factory, when he came upon a party of young women at dinner, and the following conversation took place:—'Now, there are nine of you here: how many of you are married?' 'None of us are wed.' 'Well, how much money have you got in the savings bank?' 'Weer?' 'In the savings bank: you have been earning large wages for at least seven years, and you ought to have saved a good deal by this time.' 'We niver gie it a thowt.' 'What do you do with your wages?' 'Spend them, to be sure.' 'And you've a right to spend your own wages; but if you had saved 3s. 6d. a week for the past seven years, how much would you have had?' 'Dunno know.' 'Why, you would have had between £60 and £70 now.' 'Eh, should we?' 'Yes; and if you had each had £50 and £60 in the savings bank, how many of you would have been unmarried now, do you think?' They all lifted up their hands, and one of them exclaimed, 'There would have been some clicking for us before this.'"

PERFUMES FROM FRUITS.

The fourth process I have to describe to you is that of *expression*, which is confined to the fruits of the citrine family, viz., orange (*Citrus aurantium*), bitter orange (*Citrus bigaradia*), lemon (*Citrus medica*), bergamot (*Citrus bergamia*), cedrate (*Citrus cedrata*), and limette (*Citrus limetta*). The rinds of all these fruits contain an essential oil, ready formed in small vesicles, and various means are adopted to extract it. On the coast of Genoa, they rub the fruit against a grated funnel; in Sicily they press the rind in cloth bags; and in Calabria, where the largest quantity is manufactured, they roll the fruit between two bowls, one placed inside the other, the concave part of the lower and the convex part of the upper being armed with sharp spikes. These bowls revolve in a contrary direction, causing the small vesicles on the surface of the fruit to burst and give up the essence they contain, which is afterwards collected with a sponge. The rinds are also sometimes distilled, but the former processes, which are called in French *au zest*, give a much finer essence. The three principal essences of this kind used are orange (called also Portugal), lemon, and bergamot, which all enter into the composition of eau de Cologne, and many other perfumes. They are made in Calabria and Sicily, in the months of October, November, and December, and the quantity of fruits required to make one pound of essential oil varies as follows during that time:—

	October.	November.	December.
Oranges	1,500 ...	2,000 ...	2,300
Lemons	1,500 ...	1,800 ...	2,000
Bergamots ...	1,800 ...	2,000 ...	2,300

The essence produced by squeezing the rind is yellow; that made by the machine has a green tint: the more or less ripe state of the fruit also influences the colour. The following quantities are produced yearly on an average:—

	lbs.		Fruits.
Orange ...	300,000	made with about	540,000,000
Lemon ...	500,000	,, ,,	750,000,000
Bergamot ...	300,000	,, ,,	600,000,000

—*Eugene Rimmel.*

SOMETHING LIKE EXPERIMENTS.

Professor Doremus gave the first of a series of lectures at Brooklyn, on April 17th, entitled, "Views of Life through the Medium of Science." Some of the experiments he performed are described as follows in the *Scientific American*:—"Besides the novel experiments exhibited in these lectures, the ordinary class experiments are conducted on a scale which produces the effect of novelty. For instance, in burning potassium on water, a tank was used which extended entirely across the theatre, in front of the stage; covering the whole area of the space usually occupied by the orchestra, and the middle of this tank contained several hundred pounds of ice in massive blocks; upon this water and ice half a pound or more of potassium pellets were scattered, producing most brilliant corruscations of violet and yellow sparks and flames, and filling the whole theatre with a cloud of potash. Several gallons of liquid carbonic acid were condensed, and the bar of mercury frozen by it was a yard in length and two inches in width. To exhibit the combustion of steel in the blow-pipe flame, a whole saw and half of a long sword were burned, the sparks pouring forth in a shower fifteen feet in length."

Things Talked About.

Connected with the Corporation of London, and under the control of the Chamberlain, is a fund known as Wilson's Fund, employed to assist young and respectable tradesmen, by lending small sums of money, to enable them either to extend their business or to overcome some of the difficulties which, in the outset of life, the possession of but a small capital is unable to contend with. Nearly eighty years ago, we are informed, the famous Dr. Franklin gave to Philadelphia and Boston small sums of money, to be used for the encouragement of young married mechanics who might need an occasional loan. The bequest to Boston, which amounted to $9,000 (nearly £1,800), has, after doing much service, grown to $110,000, more than twelve times its original amount. Now, the habit of borrowing money is surely not to be encouraged. But it is, unfortunately, too frequently an absolute necessity. The loan society and the pawnbroker's shop are established facts; and though they are very frequently, as we all well know, resorted to by the improvident or vicious, they are nearly as often the only means open to the deserving, but unfortunate, of obtaining the actual necessaries of life. The interest paid is high; and a recourse to their aid too often necessitates periodical visits, one transaction overlapping another, until the borrower is in full career on the road to ruin. Better would it be if such a fund as Franklin's, or as the Corporation Wilson Fund, were in existence, to which those really overtaken by a sudden disaster could resort and receive assistance, to be repaid, when the struggle was past, with moderate, not crushing interest.

A meeting has been held for the purpose of organising a working men's excursion to Dublin in August next.

The trip is proposed to be for a week or ten days, and the London and North-Western Company have agreed to carry 300 persons by railway to Holyhead, and from thence by steamboat to Dublin, and to bring them back to London, for the sum of 21s. each person, and in addition to this sum 6d. each person will be charged as registration fee, to pay the expenses of printing and advertising. A good holiday is a good thing; but it must not be forgotten that the fare is only a part of the expense. A week's residence in Dublin will cost something, and it would be a pity to place the limit of the trip there. The interest of the town would soon be exhausted, and even short trips to view the scenery around—and the Wicklow mountains and the valley of the Liffey should not be left unvisited—will cost a few months' savings. We by no means discourage the idea of the proposed excursion: only, count the cost first.

Is the regulation of the Painters' Trade Union, referred to in the following case, generally known? We trust it will be reconsidered on the first opportunity. A painter employed to paint a butcher's shop stole a leg of mutton. When put on his trial at the Middlesex Sessions, the Deputy Assistant-Judge inquired if his employer had received any character with him when engaged. The master said that they were not allowed to inquire into the characters of their servants. The Court thought it was very extraordinary. A gentleman on the jury, who said he was in the building trade, stated that a short time ago the masters wished to have a character from the workmen's former employers before taking them into their service. Upon this matter the men of the Trade Union held a meeting, and agreed not to allow the masters to exact anything of the kind from them, as they believed that the real object of it was to give the masters an improper control over their men, and prevent them from obtaining employment from any other master, in case of any disagreement between the employer and the employed. Such a resolution is evidently wrong in principle; and can only have the effect of widening the social breach unhappily existing between the employer and employed. The prisoner in this case was actually a ticket-of-leave man; a fact of which his master was ignorant. Masters have an equal right with the men to security against imposition. Most especially so, when, as in the case of a working painter, the man is sent to work in other people's houses, where, if property is stolen, the master himself is liable indirectly to suffer in reputation, and the honest fellow-workman to be suspected and prosecuted. If a master gives a false character, he is properly liable to an action for damages; and employers are not, more than other folks, disposed to incur such a risk.

The sailors' strike at London and Liverpool is exciting great interest. An "Old Commander" has published some sensible observations on the subject. He says:—"The wants of our sailors are: Better accommodation on board ship; an improved scale of diet; half-pay for their wives and families, who are left sadly off in most cases; married sailors' homes, which shall ensure that they (inexperienced in household management as they must be) shall get the value of their money, and leave their wives in respectable quarters. Experience plainly proves that when seamen can leave their wives and families favourably-circumstanced, both keep steady; but the present state of things upsets, morally, many thousands of men and women. Sailors do not so much need an increase of pay as they do a change of direction in the employment of their money, which is now wasted on drink and bad women; though, with the present high prices of provisions, an increase of pay is probably a reasonable demand."

Some of the seamen of the port of London have held a meeting for the purpose of establishing a Seamen's Benefit Society. Such an institution might become of the utmost value; and the position of the promoters, in respect to the present aspect of affairs, may be seen from the resolution unanimously carried: "That this society will not support any of its members in a demand for higher wages than their present rate, except in the event of war, when they would be guided by circumstances."

The large sum of £22,100 has already been expended in consequence of the lock-out in the Sheffield file trade. The aspect of the affair is sad indeed; and we cannot acquit the masters of a full share of the responsibility of causing it. The allowance fixed by the Filesmiths' Union at the commencement of the lock-out, for the support of the men, was at the following rate:—7s. per week to single men, and 9s. per week to married men, with 1s. per week additional for every child. This allowance has, up to this week, been regularly paid to every man, and has absorbed the sum of £1,700 per week. What an admirable provident fund might have been formed with such a sum, added to the expenditure of which is the loss of full wages to the men, and of capital and property to the employer! Can nothing be done to bring about a better understanding?

We have scarcely more encouraging news from the Clyde engineers and ship-builders. The employers, at a meeting lately held, expressed their willingness, in answer to a proposal on behalf of the workmen, to concede a reduction of the working hours to fifty-seven, but were not disposed, in present circumstances, to give an advance of wages at the rate of five per cent., as claimed by the operatives.

The Hull bricklayers have turned out on strike. They require a half-holiday on Saturdays, and extra wages, in order to make up for the loss of time which would thus be sustained, so as to keep their week's wages at the present amount. The bricklayers' labourers also demand an advance in wages. Several public works will be delayed by this movement, but in one case (the New West Dock Works) the demand has been acceded to, as time cannot be lost.

The metropolitan boot and shoemakers who have made a stand for an advance of wages have partially gained their point, several of the largest West End employers having conceded a very considerable advance.

The Birkenhead Commissioners have resolved to spend £8,000 in purchasing land and erecting public baths—a good example to other corporate bodies.

A museum in connection with the Mechanics' Institute at Bishop Auckland, Durham, is projected. It is proposed to unite in one building several fine collections of geology in the neighbourhood, which have been laboriously collected for years out of the surrounding collieries, which can never again be explored. The seams from which they have been taken have either been worked out or have disappeared out of the earth's formation. Such local museums would be of great value in districts presenting any peculiarities of situation.

The Rev. Canon Girdlestone, of Bristol Cathedral, has been alarming the farmers of the west country by urging labourers to emigrate to Lancashire. He told them that labourers—scores of them—were much wanted; and any number from Devonshire, if strong, healthy, willing, industrious, and sober, could always earn from 20s. to 25s. per week. Now, if he were a strong, active fellow, like some he saw before him, he should say to himself, "I am not going to sit down and starve here, a poor, thin, miserable fellow, with 8s. a week. I will pack up my clothes in a bundle, and go into those parts where I shall get better wages for my labour." He advised them to get rid of their homey feelings and move off. On such low wages as they at present had it was impossible they could do their duty either to their masters or their families. The Canon has preached on the subject, lectured the farmers at a tithe dinner, and addressed the labourers themselves at a Friendly Society's feast.

Co-operative Intelligence.

BIRMINGHAM FORWARD CO-OPERATIVE SOCIETY.—This society, whose head-quarters are at 12, Graham Street, has just issued its first quarterly statement, which is as follows:—"Birmingham is one of the many towns that has been stigmatised as not being able to carry out the Co-operative movement, and the question is sometimes asked, How is it? You have as much intelligence as any other town in the kingdom. We have not space enough to answer the question as completely as we would wish, but one or two reasons may be given. The Co-operative Societies that have been in existence in Birmingham before, have been established upon the principle of withdrawal of shares. The success of a society on this principle must depend, in a great measure, upon the whim of its members, for should any of them get offended they will draw out their shares, and induce others to do so too, and by this means they curtail the operations of the society. No such curtailment can happen to your society, it being established upon the principle of transferring the shares. Each member by this means will bear an equal share of profit and loss. Another advantage of your society is that each member is only required to take up two shares, instead of five, thus placing the society within the reach of a larger number of persons. Your committee feel confident that the society only wants making known to be appreciated; for it is gratifying to them, in submitting their first quarterly report, to find that they can pay five per cent. interest on capital invested, and a dividend of 6d. in the pound on members' purchases, also carrying a sum to the reserve fund. It seems to us that a working man cannot invest his money better than in the Co-operative Society. The articles we sell he requires every week. We will suppose he has his £2 paid up, and that he spends £5 in the quarter at the store. We will take the dividend at the rate of 6d. in the pound. At the end of the year his shares will be worth 26s. each, or clear gain of 12s. in the year upon his £2."

EARLESTOWN.—The twenty-second quarterly report of the Earlestown Industrial Co-operative Society, Limited, shows that a dividend of 1s. 10d. in the pound to shareholders, and 11d. to non-shareholders, has been declared. Cash received for goods, £2,031 7s. 6d.; cash paid for goods, £1,793 11s. 8½d.; profits, after paying all expenses, £176 17s.

CO-OPERATION IN MIDDLESBRO'.—A few days since a meeting, which was more numerously attended than was anticipated, was held in the Odd Fellows' Hall, Middlesbro', to take some steps towards forming a Co-operative Building Society. Ultimately a committee was formed to draw up rules for the management of the concern. The committee have since had a meeting, and we learn that it is intended to have a capital of £10,000, raised in shares of £1 each. The society will be registered under the Limited Liability Act.

WINDSOR.—The committee of the Windsor Co-operative and Industrial Society, Limited, have published their third quarterly report, in which they state that the members' contributions and purchases have been greatly augmented since their last report. The number of members admitted since last quarter is 78, while they have only had a total of 10 excluded and withdrawn, so that there are at present on the books 220 members. The committee have had in contemplation the establishment of a butchering business amongst members, but as the contributions have been slow in coming in, they have deferred the subject till the quarterly meeting. They have also opened a branch store at Slough, which they hope, with the great patience and zeal of the members appointed to conduct the same, will go on as prosperously and economically as the parent society has done. The income for the quarter was £571 8s. 1½d., showing a balance of profit of £59 19s. 11¼d., which, after paying interest on shares, &c., allowed a dividend of 2s. in the pound on members' purchases, and 8d. in the pound on those of non-members.

General Information.

CLUBS AND INSTITUTES.

PADDOCK.—The inauguration of the lately-established Working Men's Club at Paddock recently took place in the Congregational schoolroom. About 150 partook of tea, after which a public meeting and *soirée* was held, under the presidency of Wright Mellor, Esq., who addressed the meeting at some length, and said the promoters had the good wishes of many absent friends, and he hoped they (the members of the club) would follow the advice of Mr. Lupton, and "strive and work, work and strive," for the prosperity of the institution. The object they had in view was a good one, and he felt glad that working men were imitating the example of those above them in forming clubs to amuse and instruct themselves; and he (the chairman) saw no reason why the working classes should not have their clubs as well. He entirely disapproved of the rule of the club forbidding discussion on religious and political topics. They had newspapers and periodicals of all shades of politics, and he could see no objection to the members calmly and quietly discussing questions which from time to time agitated the country. After referring to the advantages of proper means of recreation provided by Working Men's Clubs, he expressed a hope that they would multiply in numbers and enlarge their borders, and that the time was not distant when they would build a place for themselves in some snug corner. He concluded by referring to the fact of the Working Men's Club in London having recently expended £9,000 in erecting club-rooms; and although at Paddock they could not expend such a large sum, depend upon it, if they went about it in earnest, they would find plenty of friends ready to lend a helping hand. The secretary, Mr. S. Sykes, then read the financial report, which stated that subscriptions amounting to £37 11s. had been received, while the fitting up of the rooms, including chess, draughts, bagatelle-boards, &c., had cost £52 9s. 9½d., leaving a debt on the institution of £14 18s. 9½d. They had 131 financial members, paying 1s. 6d. per quarter, amounting to £9 16s. 6d. The expenditure was, for rent, gas, cleaning, &c., £7 1s., and for newspapers, &c., £3 18s., leaving a deficiency on the quarter of £1 2s. 6d.; but the sale of the old newspapers, &c., fully covered it; so that the income balanced the current expenditure.

LAMBETH WORKING MEN'S CLUB.—The first quarterly meeting of this society was held, on Monday evening, in the large and convenient building called the "Ragged Schoolrooms," Lambeth Walk. W. H. Miller, Esq., presided; and Mr. Whymper, the honorary secretary, gave a short account of the past history and present position of the Club. There are about 100 members belonging to it, paying a penny a week. Premises had been taken close by, but they were far too small and inconvenient, and a great effort was to be made to build a large room at the back. There is an excellent cricket club formed by the members of this society, meeting in Battersea Park once a week, and a discussion meeting has been kept up with great spirit every Thursday evening. The Rev. H. Solly was then called on to deliver an address on the advantages of Working Men's Clubs, and was followed by the Rev. G. D. Evans, and other ministers and friends of the movement. A number of songs and glees were given in capital style by members and friends of the Club in the course of the evening, and a piece of music was beautifully played on the piano by Miss Morse. In spite of the pouring rain, there was an excellent attendance, every seat in the large hall being occupied by working men and their wives. The result is mainly attributable to the very sensible custom, now becoming increasingly prevalent, of enlivening such meetings by vocal and instrumental performances. It is satisfactory to find that these very useful societies are at last taking root on the other side of the water. For a long time Lambeth seemed utterly unable to establish or maintain a Working Men's Club; but in addition to the above, the one established some time since in Miller's Lane, and which seemed for many months in a state of

suspended animation, has recovered under the energetic efforts of the honorary secretary, Mr. Cole, and a few other friends, and it now appears to be tolerably well supported by the working men of the neighbourhood.

Rotherham and Masborough Working Men's Club and Institute.—Mr. Solly writes:—We have just received the report and balance-sheet of this excellent Club for the year ending February 28th, 1866. The latter strikes us, as showing an expenditure which in its objects and proportions is almost a model of its kind, agreeing with a shrewd observer of these Clubs that a balance-sheet gives a great insight into their working. The report itself is very satisfactory, and the following paragraph in it is especially worth quoting:—"The evening classes, lectures, debates, and recreation meetings are, upon the whole, well attended, and the improvement manifested in the scholars evinces their desire to learn, and reflects great credit on those gentlemen who have voluntarily come forward as teachers." The premises now occupied by the Club will shortly be wanted by the South Yorkshire Railway Company, hence the Committee remark—"This is a question which demands serious attention. Efforts have been made to secure suitable premises in the town, but there appear to be none sufficiently convenient for the growing requirements of the Club. Under the pressing circumstances, your Committee, after mature consideration, determined to test the feelings of the working men by convening a meeting for the purpose of discussing the necessity of building suitable premises. Several public meetings were held, which resulted in a project, now in formation, called the 'People's Hall (Limited),' in £1 shares, payable by instalments. Although this project is entirely unconnected with the Working Men's Club, arrangements would be made in the erection to provide suitable rooms for their requirements." Since the above report was written, it seems probable that a coalition will take place between the Club and the Mechanics' Institute in the town, as the latter possesses a fine building, but, as usual, no mechanics belonging to it. The report concludes thus, and we heartily congratulate the Committee and members on the satisfactory results they have been able to achieve:—"At the close of this second year of the Club's existence, your committee congratulate the members upon the liberal support they have received, and the favourable results this institution is working. Now that the freshness and novelty have worn away, a fair view of its real strength is shown, and they believe that the Working Men's Club has established for itself a permanent footing amongst the institutions of the town."

Coventry.—The committee of the Working Men's Club, in presenting the report of the third year's proceedings, congratulate their fellow-workmen upon the position of the institution. Established, in the first instance, by the kindness of friends, as a place of unobjectionable resort in a time of want of employment, it is with satisfaction that your committee may now look upon the last two years as an indication that the working men are disposed to maintain, by their own exertions, a place for mutual improvement and social intercourse. The Working Men's Club is deeply indebted to the exertions of many young men, whose services in the Tuesday evening entertainments reflect great credit upon themselves. A most substantial proof of the use of the institution is, that the net receipts have amounted to £18 3s. 11d., after a large outlay in what may be called properties. The committee trust that these friends will continue their exertions, and that every year improvement will be made. The circulation of the library has been satisfactory; and the committee refer with pleasure to the financial statement, which shows a balance of £8 1s. 2d.

EMIGRATION.

Value of European Emigration to the United States.—The United States receive annually from Europe an enormous tribute in two kinds—men and money. Mr. Carlyle has calculated that a live European man with his five fingers must be worth more than a horse. He probably is worth a very great deal more to a country which can provide him with land and occupy him with labour. But no emigrant comes empty-handed, like a dumb animal. Amongst the poorest class of immigrants the average sum which each man brings is £13 12s. Amongst the higher class it has been estimated at £36. We must, however, reduce this sum considerably in practice, because enormous amounts are remitted by the immigrants to their friends in Europe, to enable them to follow their example. The money, therefore, brought by each settler has not unfrequently been derived immediately from the very country to which he returns it. But if we were to reckon that every able-bodied man brought nothing but himself, like Moses on his return from the fair, the value of the 200,000 or 300,000 annual immigrants would not be sensibly diminished; for America can set them to work, as soon as ever they arrive, on the most profitable of all occupations, in a country where the soil is untouched, and the means of communication unlimited. Not quite one-third of the vast territory of the Republic, in size somewhat larger than Europe, has hitherto been surveyed, and "seven-eighths of the entire population are engaged in agricultural pursuits, or in the various professions and trades materially dependent thereupon."

Correspondence.

**** We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* Working Man, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*

We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

A LESSON IN COURTESY.

To the Editor of the Working Man.

Sir,—You have published some extracts from Mr. Rupert Kettle's book on "Strikes and Arbitrations," and I have met with other passages which induce me to recommend it to others as a good book. I do not propose to attempt to review it; that task must be left to more practised hands. But the author relates an anecdote in reference to one of those apparently small matters, which really involve a principle, and sometimes produce great results. This is the story:—"When the mining district of South Staffordshire was convulsed by the last great strike, and when enough loss had been sustained to prove that both parties were thoroughly in earnest, a meeting was arranged between a deputation from the masters and a deputation from the men. The meeting was fixed for a certain hour at one of the principal hotels in the neighbourhood. At the appointed time the workmen's delegates went to the place of meeting. They were ushered into a grand room, in which the masters had been assembled some hours before. The men found the negotiants whom they were to meet upon equal terms already seated at a long table, with writing materials before each, and their chairman presiding. The men's delegates were directed to a bench at the end of the room as the place provided for them. Here they sat in a row, dangling their hats. When all were seated, and the scrutinising eye of ten-master-power was upon them, the masters' president opened the negotiation with—'Well, what have you chaps got to say for yourselves?' That question cost the district an incalculable sum of money—positively tens of thousands of pounds. The asking of it was, indeed, nothing less than a public calamity. Yet the masters' chairman could have had no intention to wound the susceptible pride of the men, for he was naturally most genial and kind-hearted."

Doubtless he was; but he seems to have possessed the unfortunate gift of being able to say very irritating things. His words would not, probably, have rankled as they did if it had not been for the slight cast upon the men by seating them on a bench while the employers were comfortably established in easy chairs and at a table. The masters were not assembled as a bench of magistrates, but as business men wishing to discuss with other business men matters on which they were equally interested. True courtesy never ostentatiously parades differences of condition, and consequently obtains more real respect.

I believe the men were well disposed to discuss temperately the matters in dispute. I am sure they would not have wantonly insulted the employers; but they had a perfect right to be treated as men, and that is very nearly the same as being treated as gentlemen. "You chaps" would irritate anybody; and I, for one, do not wonder that matters grew worse than before.

I do not write for the purpose of raking up a past grievance, but because in similar circumstances a similar mistake might be made. A great many evils might be remedied peaceably, if people would only approach the discussion in a mutually respectful and conciliatory temper. At least, that is the opinion of Piston-rod.

THE PROPOSED PEABODY STATUE.

To the Editor of the Working Man.

Sir,—I have read in the papers that it is proposed to erect in the metropolis a statue of the kind-hearted and liberal-minded George Peabody, as a lasting memorial of his munificent gift to the poor of London. With the feeling which has prompted this expression of grateful thought I have no fault to find, but surely it might have suggested something more appropriate than a statue, which in this country often becomes a butt for ridicule. Why not have the Peabody Institute, the Peabody Museum, or some similar institution, established expressly for the use of the working classes? Such an institution would be in harmony with the spirit which led George Peabody to devote so large a portion of his wealth to the erection of improved homes for working men. I beg to commend the idea to the promoters of the Peabody testimonial, and feel assured that if they adopt it they will not find the working classes of London backward in subscribing to the fund.—I am, Sir, yours respectfully, A Practical Man.

SUNDAY TRADING.

To the Editor of the Working Man.

Sir,—Much has been said about the evils of Sunday trading, and the necessity for putting it down. Now, I do not wish to defend the system, but it strikes me that the attempt to suppress it is being conducted on an entirely erroneous idea as to its real causes, the principal of which is, undoubtedly, late shopping on Saturday evenings; for, although many of the Sunday purchasers are those who have deferred their purchases until the last moment, the great majority consist of those—such as costermongers, shop porters, and the like—whose occupation is not over until ons or two o'clock on Sunday morning. These people have no opportunity of making their purchases on Saturday evening: they must wait until the Sunday morning. If the Saturday night shopping could be thrown earlier into the day; or, still better, if wages could be paid in the middle of the week instead of at the end, many of these now detained in their avocations until midnight on Saturday could be released from their labours, and make their purchases on Saturday night, thus diminishing the number of Sunday buyers. Sunday trading will never be put down, but would rather be increased, by any attempt at legislation.

Jack Plane.

TO CORRESPONDENTS.

Query.—It is said that of the deceased Presidents of the United States, Washington, Madison, Monroe, Harrison, Tyler, and Tayler, were Episcopalians; Jefferson, John Adams, and John Quincy Adams were Unitarians; Jackson, Polk, and Lincoln were Presbyterians; Van Buren was of the Dutch Reformed Church. The surviving Presidents are Filmore, a Unitarian; Pierce, a Trinitarian Congregationalist; Buchanan, an Episcopalian; and the present Chief Magistrate, Johnson, who is a Presbyterian.

A Poor Ignorant Ploughman.—We regret that we cannot see our way to use your letters, creditable as they are to your heart and head.

Non-Elector.—The discussion having closed, your letter cannot appear. Had it been forwarded earlier, we would gladly have inserted it.

H. Bool.—The Ophthalmic Hospital, Moorfields.

T. E. J.—Procure the London University Calendar.

Typo.—The first number of the *Weekly Political Register*, with which William Cobbett's fame as a writer is so intimately associated, appeared in January, 1802.

T. S.—The Stalybridge Mechanics' Institution was established September 7th, 1825.

Stephen.—The latest return of the cost of our iron-clad ships is as follows: *Warrior*, £310,000; *Black Prince*, £299,000; *Defence*, £217,000; *Resistance*, £255,000; *Hector*, £244,395; and *Achilles*, £389,219.

C. W. (Leeds).—Thanks for your offer, but our arrangements are complete.

Thomas Briggs.—Please repeat the question alluded to.

J. W. B.—Your wish shall be complied with.

Une Mere.—The subject is important, and shall not be lost sight of.

Banker.—We do not advise in such matters.

*** We are compelled to decline a letter which we have received, signed, "A Member of the Operative Masons' General Union."

W. W.—You must contribute towards the support of the child until it is fourteen years of age. The children would not be allowed to work, save as "half-timers." The third question should be submitted to a respectable solicitor.

Miner.—The recent accidents with the new explosive agent have induced Mr. Nobel to turn his attention seriously to the subject of rendering nitro-glycerine non-explosive and explosive at pleasure; and he is now enabled to state that, by mixing the nitro-glycerine with methylic alcohol—a cheap spirit, popularly known as spirit of wood—the nitro-glycerine is rendered unexplosive, either by percussion or heat. When required for use, water is added, which absorbs the spirit, and the oil sinks to the bottom of the vessel, whence it is drawn by a syphon, and its explosive nature thereupon found to be restored. Experiments for testing the value of this discovery have already been made in America, and given highly satisfactory results.

A Preston Lad.—"Christmas Day and Good Friday must be kept as holidays; and, besides, there must be eight half-holidays each year—four of these must be between the 15th March and the 1st October. Notice must be given the day before, and be fixed up at the entrance of the factory, and in such other place as the inspector may direct."—3rd and 4th Wm. IV., c. 108; and 7th Vict., c. 15.

A Finisher.—There are several provisions for fencing machinery, and regulating the size and ventilation of workshops. The informations to be laid before two magistrates, within five miles of the place where the offence occurs. No appeal is allowed, except the offence is punishable by fine or imprisonment, or the penalty is more than £3.

Pick and Spade.—The first mention of coal appears to have been made about 2,000 years ago by Theophrastus, a pupil of Aristotle. He stated that it was found in Liguria.

W. L.—In France, in 1670, during the reign of Louis XIV., it was ordered that master masons, carpenters, and slaters should give their names and addresses to the commissioner of police for their quarter, and be always prepared to turn out with their men immediately on an alarm of fire being given. They were to be paid for working at fires, and heavily fined if absent.

NOTICE.—The readers of the "Working Man" are solicited to bring the following announcement under the notice of any of their friends whom they may think will be interested.

Metropolitan and Provincial

WORKING CLASSES' EXHIBITION and INDUSTRIAL FESTIVAL, to be held at the AGRICULTURAL HALL, London, and opened on SEPTEMBER 3rd, 1866.

TO EXHIBITORS.

Contributions of Skilled Workmanship, or Amateur Productions, will be accepted from all parts of London, the Provinces, Scotland, Ireland, and the Colonies. For the benefit of Provincial Exhibitors, the Railway Companies have liberally offered to return unsold goods free, so that the expense of carriage will be but half the usual charge. Application for space to be made at once.

SPECIAL PRIZES.

The Council of the above Exhibition have much pleasure in announcing that, in addition to the MEDAL OF MERIT, designed for the occasion by J. S. and A. B. WYON, Esqs., the following SPECIAL PRIZES have been liberally offered by the gentlemen named, for the production of Articles to be Exhibited at the Agricultural Hall in September next, namely—

£15 0 0 in Money, or Silver Cup, for the MOST USEFUL INVENTION. Open to all Classes. The Gift of the Directors of the Agricultural Hall Company.

£10 0 0 in Money, or Silver Cup, for the best PAINTING IN OIL. The Gift of the Directors of the Agricultural Hall Company.

£5 0 0 in Money, or Silver Cup, for the second best OIL PAINTING. The Gift of C. COMFORT, Esq.

£5 0 0 in Money, for the best WATER-COLOUR DRAWING. The Gift of J. HARRIS, Esq.

£3 3 0 for the best GOLD BROOCH and EAR-RINGS, of Original Design, which can be sold for £10. (Sale for that sum to be permitted if required.)

£2 2 0 for the best pattern, Birmingham make, GILT BRACELET, BROOCH, and EAR-RINGS, which can be sold for £3 3s. (Sale for that sum to be permitted if required.)

£2 2 0 for the best Specimen of WHITBY JET JEWELLERY.

£2 2 0 in Money, for the best WORKING MODEL of a STEAM-ENGINE. The Gift of W. J. W.

£2 10 0 for the best ARTICLE OF UTILITY, made by an Amateur. The Gift of B. MURRAY, Esq.

£2 2 0 and a Silver Medal, the Gift of R. MURRAY, Esq., for the best WORKING MODEL of a MILL to grind Stale Crusts into Flour.

£2 2 0 for the best PEN-AND-INK DRAWING. The Gift of — SPEAKES, Esq.

£2 2 0 for the best Original Contrivance that may be suggested for improving the Fittings of WORKMEN'S DWELLINGS.

£2 2 0 for the best Specimen of SHEFFIELD CUTLERY. The Gift of T. RUDKIN, Esq.

£2 2 0 for the best Pair of LADY'S BOOTS. The entire work to be done by Exhibitor.

£2 2 0 for the best Specimen of INLAYING IN WOOD. The Gift of C. A.

£2 2 0 for the best Specimen of WOOD CARVING. The Gift of J. S. and A. B. WYON.

£2 2 0 for the best Specimen of CABINET WORK, made by an Apprentice who has served not more than four years to his trade. The Gift of Mr. I. HAYNES.

£2 2 0 and a Silver Medal for the best Specimen of ORNAMENTAL TYPOGRAPHY, consisting of a Quotation from Shakespeare, displayed and Printed in Colours, to occupy a royal 8vo page.

In addition to the above, the

EXHIBITION SILVER MEDAL

will be awarded to the Exhibitors of the best Specimens of

Household Furniture.	Stained Glass.
Hammered Iron-work.	Artificial Flowers, from Nature.
Watch-Case Engraving.	Working Model of a Steam Vessel.
Engraving on Glass.	Statuette, in Plaster, or other Material.
Coventry Ribbons.	
Design for Paper Hangings.	
Embossing in Metal or Electro-Plate.	

☞ *Medals will also be awarded for other Articles which may be deemed worthy of especial distinction.*

All objects must be the work of the Exhibitor. In cases where Articles are the property of Employers, the name of the firm permitting their exhibition will be given in the Catalogue.

FORMS OF APPLICATION FOR SPACE may be obtained by sending a stamped and directed envelope to the Secretary, Mr. W. J. WATTS, 7, Birchmore Terrace, Cardington Street, Hampstead Road, London, N.W., or by application to any of the Honorary Agents. To be returned, filled up, on or before June 30.

Steamboat Excursion to HAMPTON COURT, Richmond, Kingston, or Teddington, by one of the new Citizen Steamboats, with improved Saloon Accommodation. This boat will leave LONDON BRIDGE (weather permitting) every SUNDAY and MONDAY, at Ten o'clock, calling at all piers, and returning in the evening.

Sec.* [8

The Original Chlorodyne, Invented by R. FREEMAN, Pharmaceutist, is allowed to be one of the greatest discoveries of the present century. It immediately relieves and cures Coughs, Colds, Consumption, Influenza, Bronchitis, Asthma, Whooping Cough, Cramp, Spasms, Gout, Diarrhœa, Dysentery, &c.

EARL RUSSELL communicated to the Royal College of Physicians and to Mr. Freeman that he had received information from Manilla that the only remedy of any use in Cholera was Chlorodyne.—*Lancet*, Dec. 31st, 1864. See *Times*, Nov. 14th, 1865.

Freeman's Original Chloro-DYNE.—The *Medical Times*, Jan. 13th, 1866, states—"It has an immense sale amongst the public, and is prescribed by scores of orthodox medical practitioners, and, of course, it would not be thus singularly popular did it not supply a want and fill a place."

Freeman's Original Chloro-DYNE engraved on the Government stamp outside every bottle. Sold by the Inventor and Manufacturer, R. FREEMAN, 70, Kennington Park Road, London, S., and most Chemists. In bottles, ½ oz., 1s. 1½d.; 1½ oz., 2s. 9d.; 10 oz., 11s.; 20 oz., 20s.

Caution! Beware of spurious, deceptive, and dangerous imitations. Ask for Freeman's Original Chlorodyne, and see that you have none other. [9

BY HER MAJESTY'S ROYAL LETTERS PATENT.

Morrison's Archimedian HEM-FOLDER for the Sewing Machine and the Finger. Manufactured solely by

JOSEPH GILLOTT,

Metallic Pen Maker to the Queen, Victoria Works, Graham Street, Birmingham.—Drawings and particulars forwarded on application. [23

Gathered from the Waters. For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1857, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the Shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,600 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C. [10

The Planet Permanent Building

AND INVESTMENT SOCIETY, Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and full further information may be had of EDMUND W. RICHARDSON, Secretary.

B. Prew's Wardrobe.

At this splendid new building you'll see a display
Of all the new fashions, the first of the day;
If well dress'd you'd be, and at lowest price, too,
"Then come to my wardrobe," says Benjamin Prew.

If frock or Oxonian you should require,
And really are choice in this part of attire,
Wishing best of material, with style that is new,
"Then come to my wardrobe," says Benjamin Prew.

If a coat you should want, for business or dress,
Or a waistcoat of which you'd approval express,
Or trousers to fit, cut on system quite new,
"Then come to my wardrobe," says Benjamin Prew.

If you have any boys, and would see them well dressed,
In clothes to wear well, and become them the best;
Or want Knickerbocker suits for young children, too,
"Then come to my wardrobe," says Benjamin Prew.

Every one buys of Prew, so well known is his name.
If you study your int'r'st you'll just do the same;
If you'd dress in the fashion, and save money, too,
"Then come to my wardrobe," says Benjamin Prew.

Children's Knickerbocker Suits from	12s. 6d.
Boys' Eton, Harrow, and Rugby Suits	21s. 0d.
Boys' Cricketing Suits	21s. 0d.
Gentlemen's Overcoats, from	12s. 6d.

Ladies' Riding Habits, Liveries, &c.

B. PREW, Tailor, Hatter, Hosier, and General Outfitter, the great Metropolitan Wardrobe, 294 and 295, High Holborn (15 doors west of Chancery Lane). [4

Official Judgment.

THERE is no conspiracy to suppress originality in this country. Even eccentric people have tolerably fair play. The public get sufficiently well bored by what may be termed the "regulation" people, and are glad enough of a little variety occasionally. Yet it must be owned that when any official person proposes to do anything which has never been done before, he is pretty well "set upon." A critical contemporary has taxed its powers of complaint (which are in a healthy state by reason of being a good deal exercised) in condemning a suggestion made by the South Kensington Committee of the Paris Exhibition, that examples of the literature of England should be supplied for the inspection of visitors to the general International Industrial Collection of Paris. There is nothing to be said against such a proposal which may not also be said against every form of mechanical exhibition. Some worthless articles, sent from unworthy motives, will be sure to creep into any public collection. Many contributors will be actuated by motives of vanity, and others will overrate the intrinsic value of their work. It is clear that the chance of this must be taken, or no exhibition could ever be got together. And if a vast expository exhibition of the industries of Europe is to take place, it is difficult to see why literature should not form a part, and especially its periodical productions; and to this end the Council of Education have invited specimens to be sent in of each newspaper, review, literary, artistic, or scientific journal, magazine, tract, or pamphlet, play, street-ballad, and the like, published in Great Britain, or in any of the colonies of Britain, during the year 1866. The contents or merits of these productions of the press are not in question. Whether the pamphleteer is right in his view—whether the new dramatist is likely to restore or renew the fame of Shakespeare—whether the new street-ballad is destined to arrest the ear of a future Macaulay, or elicit the approval and selection of Mr. Palgrave, are not questions which concern the Council of Education. Their object, and a very proper object it seems to us, is to present to the continental visitors to the Exhibition at Paris, examples of the fertility and versatility of the British press. The nature of its productions will be instructive, apart from the character of the productions themselves. Their variety and typographical execution—their style and sizes will have interest for the literary, as well as the printing world of Europe.

GEORGE GLENNY, F.H.S.
(From a Photograph by Maull and Co., Fulham Road.)

Mr. H. Cole has been censured for this design. As for that, he fares no worse than any other public servant who forms opinions for himself, and endeavours to take a useful initiative. The general policy of all officials is to do nothing. So long as they keep inactive and walk in the somnolent paths of routine, they escape censure. The public have no right to complain of this, if they acquiesce in condemnations whenever a public servant does anything. He may be wrong in what he does; in such case, let the error be pointed out, but it ought to be done with some consideration, and some praise ought to be given to that public servant who does anything. A great politician once said, "The errors of juries ought to be respected;" and we should say that the very errors of a public servant, who takes any initiative, ought to be judged with discrimination. There is no question that the whole of our public departments would be ten times more useful and better conducted than they are, if officials had the courage to act more on their own judgment.

In private, commercial, and business companies, practical suggestions of great value are continually made by persons engaged in one department or other. As respects mechanical inventions, it is well known that the greater number proceed from practical working men; while, in official quarters, suggestions and improvements rarely transpire. There routine rules. To overcome this organised inertia is one of the objects which friends of public progress set before themselves. It is, however, discerned to be good policy to encourage official thought. Men who will run risks, and take trouble to incite improvements, are to be applauded. There is a wealth of enterprise and amendment locked up in official departments. Most officers know how much better things could be done than the way in which they are transacted, but it is deemed prudent in an officer to hold his peace. And they will hold their peace, unless public encouragement is extended to every effort of usefulness they make. Even where the effort itself is a failure, the merit of making the effort should be distinctly credited. This policy would make better things possible another time.

George Glenny, F.H.S., the Working Man's Gardener.

LORD BACON describes gardening as the purest of all human pleasures, and as the "greatest refreshment to the spirit of man." But there is another interesting and no less established fact, which is, that gardeners, amateur and professional, enjoy better health and live longer, as a rule, than the followers of other occupations. Parkinson, herbalist to Charles I., died at 77; Switzer, a noted gardener in the time of Charles II., at 80; Evelyn, the compiler of the first garden almanack, at 86; Bobart, the supervisor of the Botanic Garden at Oxford in the seventeenth century, died at 85; Philip Miller, the greatest horticulturist of his day, at 88; Abercrombie,

the author of "Every Man his own Gardener," at 80; Dr. Duncan, the founder of the Horticultural Society of Edinburgh, at 83; and as many names could be given of persons now living, at advanced ages, who, it is but reasonable to suppose, owe their longevity, and their ability to enjoy it, to the healthy out-door exercise which the practice of gardening necessitates. This being admitted, the importance of encouraging a taste for horticulture among the working classes of large towns is self-evident; and he who labours to popularise as a recreation that which tends to sustain the health of the sedentary worker, besides exercising a beneficial influence on the mind as the beauty of Nature becomes developed under his care and observation, performs a service which can scarcely be too highly valued. To this public service has been dedicated the career of the veteran gardener whose portrait this week illustrates our pages, and whose name must be familiar with every one who has taken an interest in floriculture at any time during the last forty years.

Mr. George Glenny was born in London as far back as 1793, when all Europe, as well as himself, was in arms. He was apprenticed to a mechanical business, but having been taken by his father to see the tulips at a nursery in Walworth, where they were grown with remarkable success, he became enamoured of floriculture, and determined to try his hand at tulip growing forthwith.

Although indulged by his parents, and encouraged by many friends, tulips were rather above his means, for in those days they commanded very high prices. Determined, however, to obtain possession of the coveted bulbs, he entered into an arrangement with a nurseryman living in the City Road to purchase a whole bed of tulips for £20, unknown to his parents, to be paid for in instalments of 5s. per week, out of his pocket money. After having made some half-dozen payments, the youthful customer was astonished one day to find his purchase brought home without notice, and a demand made for the balance. This, of course, caused a dispute, which began in an under-tone on account of the secrecy of the transaction, but ended in an open quarrel, the noise of which soon brought the father to the door, and the facts had to be explained. A friend was called in to judge of the value of the tulips, when it was discovered that they were almost worthless, so the matter ended by the unscrupulous dealer having to take back his bulbs and return the money. This led, however, to Mr. Glenny purchasing for his son the stock of a grower in Spitalfields, a locality then celebrated for amateur gardeners, and from that time he became an enthusiastic florist.

The success which attended his efforts to cultivate and improve the growth of ornamental plants soon brought him into association with the most celebrated horticulturists, and he lost no opportunity of increasing his practical knowledge, or of displaying the results of his industry at the various metropolitan and provincial flower shows. In the course of a few years he took no less than 300 prizes, chiefly for tulips, ranunculuses, dahlias, geraniums, roses, and auriculas; and on one occasion, having invited fifty-seven guests to partake of his hospitality at Worton, where he carried on his professional pursuits, he had the gratification of placing a silver prize cup before each of his friends.

Mr. Glenny's first attempts at literary composition, which were not confined to the subject of floriculture, appeared in the *Antigallican Monitor*, and other unimportant magazines; but about 1820 he wrote a series of letters, which appeared in the *British Luminary*, of which paper he was afterwards appointed editor; and subsequently he became associated with the staff of a daily paper entitled *The British Press*. After this he undertook the editorship of the *Royal Lady's Magazine*, which numbered among its contributors some of the leading writers of the day, including the Ettrick Shepherd, Miss Pardoe, Miss Porter, Miss Mitford, the Misses Strickland, and Mr. Mudford. About 1832 he commenced the *Horticultural Journal*, which was followed by the *Gardener's Gazette*. In the latter paper he drew public attention to the mismanagement of Kew Gardens, which resulted in a commission of inquiry, and ultimately in a complete reform in the conduct of the establishment. The extent of this change may be gleaned from the remarks of Dr. Lindley, who took an important part in the proceedings connected with the investigation, and described the state of things at Kew as follows: "You rang a bell by the side of a wooden gate, which of itself was perfectly emblematic of the secrecy, the unnatural privacy of the working principle within. You were let in as if by stealth, as if the gate-keepers were ashamed to see you come, or you yourself were ashamed to be seen there. And when you were there you were dodged by an official, as if you were likely to carry off the St. Helena willow tree in your button hole, or one of the smaller hot-houses in your waistcoat pocket. You entered unwelcome, you rambled about suspected, and you were let out with manifest gladness at your departure. How gratifying is the contrast now!"

Besides editing several other similar publications, many standard horticultural works of a popular character have emanated from his pen, while, for the last twenty years, not a single week has passed but he has contributed articles on the culture of flowers, fruits, or vegetables, in one or more of the current periodicals of the day. Taking into account the fact that Mr. Glenny is a self-taught man, both as a florist and a writer, his career is a remarkable example of what may be accomplished by untiring perseverance and indomitable will.

It is the fate of enthusiasts to make occasional mistakes, and the career of Mr. Glenny is no exception to the general rule. Had he confined himself to speculations connected with the special interest he advocated so well, and about which he knew so much, he might probably have become a prosperous gentleman long since. Some years ago, however, he became enamoured of politics, and was induced to engage in a somewhat singular undertaking. On the reduction, in 1836, of the newspaper stamp from 4d. to 1d., the contraband "unstamped" was succeeded by several cheap papers, in which ultra-democratic principles and infidel opinions were advocated, with a virulence now, happily, unknown. Believing the influence exercised by these papers to be pernicious and a hindrance to real progress, Mr. Glenny proposed buying up these rabid members of the fourth estate, with the intention of continuing their issue as good cheap newspapers for the people, purged of all political and irreligious matter of an offensive kind. To carry out this scheme, he had received promises of support from several noblemen and gentlemen of influence, and he accordingly purchased Hetherington's *London Dispatch*, the *Trades' Newspaper*, the *London Mercury*, and other papers. As might have been expected, the result of the speculation proved a loss, amounting to upwards of £2,000, and this not being refunded to him as promised, sufficed to cure him of his political inclination.

Mr. Glenny has been associated, from time to time, with various public movements. On the death of the Duke of York, whom he knew as a patron, he called a meeting of noblemen and gentlemen at his house, at which Earl Cathcart presided, and proposed the erection of a monument to his memory, which was ultimately carried out under the presidency of the Duke of Wellington; and to a similar effort Greenwich Hospital owes the monument to Charles Dibdin.

During the period of Mr. Glenny's career, the art of improving flowers by cultivation has made rapid strides; and to him is, no doubt, due the credit of having taken a prominent part in bringing florists' flowers to their present state of perfection. When he commenced his well-known papers on the properties of flowers, about the year 1832, there existed no established standard of quality whereby to judge the merit of new varieties, and the opinions he advanced as to the possibility of improving the formation of certain flowers—such as the verbena, the chrysanthemum, the cineraria, &c.—were viewed as chimerical by most of the contemporary writers on the subject. He has, however, lived to see his theories adopted; his so-called impossible standard of perfection reached, and even surpassed; and his name mentioned as an authority in every department of horticultural operation.

Although in his seventy-fourth year, Mr. Glenny still retains full possession of his faculties, contributes to the press, and pursues his studies in his garden at Fulham. We understand that an effort is being made to present him with a public testimonial as an acknowledgment of the services he has rendered, and that Her Majesty has contributed £50 as an indication of her interest in this well-deserved compliment to the Working Man's Gardener.

*Condition of the Working Classes in Ireland.**

We have already referred to the condition of the Irish farm labourer, and purpose now directing attention to other classes of the sons of toil in "the Emerald Isle." There may be some necessity to remark here that, owing to emigration, labour is becoming scarce in the rural districts; and this present spring has seen the labouring man receive 10s. and 12s. a week and his food, in even the more backward localities of the country. Twenty years ago, the writer knew men glad to get 2s. and 3s. a week, with inferior food. So much, *en passant*, on the great change which has taken place in the wages of the agricultural labourer in Ireland.

Manufacturing industry is extending in various parts of the country. Belfast is, of course, the great centre of manufactures—it is to Ireland what Manchester is to England; but, just as there are many manufacturing towns in England besides Manchester, so there are many in Ireland besides Belfast.

In the province of Ulster, there are extensive manufactures carried on at Lisburn, Lurgan, Portadown, Armagh, Gilford, Banbridge, Dromore, Ballymena, Carrickfergus, Ballymoney, Coleraine, Londonderry, Strabane, Drogheda, and other smaller places. The linen trade is the chief feature in the manufactures of these towns; but with this branch of business is associated many others, less or more dependent upon it. There are bleach-mills, directly connected with the linen trade; foundries, in which machinery is made for use in the factories; iron ship-building, as at Belfast, Dublin, Cork, and Drogheda; and these and other branches of business give occupation to hundreds of thousands of operatives of both sexes.

In Dublin, the flax, cotton, woollen, and silk manufactures are carried on. Irish tweeds and Irish tabinets are known everywhere. The former are too often imitated by an inferior article; but the poplins or tabinets of the Coombe cannot be very readily produced in any form elsewhere. Iron ship-building, sugar-refining, and other trades, are also extending in the Irish metropolis. At Cork, Carrick-on-Suir, Portlaw, Waterford, and other places in the south of Ireland, manufactures are also extending and giving increased employment amid a decreasing population.

The result of this is, that the rate of wages is much higher now for skilled labour in Ireland than it was twenty years ago. A young woman in any of the mills of Belfast can make from 6s. to 20s. a week, according to her age and skill in her employment. A weaver of experience, who can attend two looms, will make 18s. or 20s. a week; while linen-lappers and girls attending sewing-machines in factories where shirts, as well as the linen, are made, earn equally good wages. The males employed in these factories, from the mere lads who attend the scutching-machine to the book-keeper and cashier, all receive salaries quite capable of keeping them as comfortable as the same class in England. In Belfast—which is a new and rapidly-rising town—you will find these classes living in neat and comfortable houses, built specially to meet their requirements. In this respect there is no town in the three kingdoms so well provided. Every working man in Belfast may have his own house at a cheap rent. There is no necessity for any family to live in a room. Houses provided with every accommodation for a working man's household can be had at rents of from £6 a year upwards. Street after street of these various classes of dwellings is to be found, and they are extending daily. This is a great advantage in Belfast, with its teeming population. A differential system of rating in Belfast has done much to promote the building of houses for the working classes. When the borough rate on all premises valued over £20 a year is 3s. in the pound, it can only be 1s. 6d. on all houses valued under £20; and on all houses valued under £8 a further deduction of 25 per cent. on the 1s. 6d. in the pound is to be made if the rates be paid before the 31st of August, we believe. Sir Richard Griffith's valuation, on which all rates are levied in Ireland, is from 25 to 33, or even 40 per cent. under the letting value. The reader will see, from this, that the erection of dwellings for the working classes is greatly encouraged by this

* Concluded from page 131.

system of rating. Whether it be a system otherwise based on any sound principle it is not for the writer to discuss here; but that it has worked well in providing comfortable houses for the working classes in Belfast, is a fact which cannot be disputed.

Perhaps there is no manufacturing town in the United Kingdom where the children of the working classes can so readily obtain a sound education. Every factory, almost, has its National school attached; and there is scarcely a block of streets throughout the town without one or two schools. Every place of worship has its school—some of them a dozen or score of schools—conducted under the system of National Education, giving united secular and separate religious instruction, as the parents of the children desire. With the working of the Factory Act and the National schools, the children have years and opportunities to become educated; yet, from one counteracting cause and another, many of the young enter the mills very deficient in education.

The necessaries and comforts of life (coal excepted) can be had, on the whole, rather cheaper in Belfast than in English towns; and, with wages good, the condition of the working classes is equal to anything which exists in either England or Scotland. There need be no one idle in any part of Ulster. There is employment for all at very good wages, and none may want all that is required to make home comfortable and happy, except through their own faults. We cannot say that this is so in every case; for, as in too many English towns, the publican thrives on the earnings of the working classes, which they ought to take to their own homes to render them all that they ought to be. We know working men into whose homes £3 per week could be brought to make them comfortable, but the publican gets £2 5s. of the amount, and 15s. is all that finds its way into the working man's dwelling. But "how could they live without a glass of something?" And glass after glass follows, until their homes are made hovels, and their lives miserable.

The Saturday half-holiday system prevails at all factories in Belfast, and an annual holiday in the summer, when the mill-owner gives his "hands" an excursion to the country by train, and some nobleman throws open his demesne for their recreation. These kindnesses are always well reciprocated by the *employés;* and seldom or never has any trouble arisen in Belfast from strikes amongst factory hands. Occasionally a question of wages has been in dispute, but good sense has prevailed, and everything has been amicably adjusted.

The influence of religion prevails largely in the great centre of Ulster. We regret that it has too often been exhibited in party riots and sectarian animosities; but, taking all classes into account, you find none ignorant of all the great fundamental truths of Christianity. Indeed, this, as we previously mentioned, is applicable to the entire population of Ireland—neither atheism nor infidelity can be found in the land amongst any class of her people.

What we have said of Belfast applies almost equally well to other manufacturing towns in Ulster, except that in no other is house accommodation so good. Lisburn, Lurgan, Ballymena, and even Londonderry, have some very miserable lanes and alleys, in which the working classes live in wretched homes, made more wretched still by the drink. Most of these towns are peculiar for some one class of manufactures, even in the linen trade. Lurgan is the great seat of the cambric manufactories, and its cambric handkerchiefs are unrivalled. Londonderry, on the other hand, is noted for being the seat of shirt manufacture, from the linen turned out of the mills of Belfast and other places. Wages are, as a rule, not so high in these towns as in Belfast; but house rent is less, and the cost of provisions much less, viz., potatoes, eggs, butter, milk, and other produce of the surrounding farms.

The workers in foundries, in ship-building yards, bleach-greens, and other places, are all able to earn fair wages, and can, on the whole, live as comfortably as in England, Scotland, or even America. Where wages are high the cost of living is equally so, and the comforts of life to be obtained are thus all as readily reached almost in one country as the other.

In Dublin, Cork, Limerick, Waterford, and other places in the south and west of Ireland, manufactures are not so extensive, and the means of employment for all are not so abundant. But matters in this respect are improving: factories are springing up in one place after another, and, with attention to industrial pursuits, the future of Ireland is full of promise.

It may be asked, If the condition of the working classes be thus hopeful in Ireland, why do we hear so much of Irish grievances and Irish distress? We distinctly and emphatically affirm, that there is no ground of "Irish distress" but is within the reach of the Irish people themselves to remedy; and working men can improve their own condition here, as elsewhere, without the aid of Government. We have a class of people in Ireland who seem to think that Government ought to do almost everything for them. We repeatedly hear a cry for "a paternal Government." If the harbours are to be improved, quays built, employment created, it is too often asked, Why does the Government not do it? We require to learn a greater spirit of independence of Government, and dependence in each other. If this latter principle could be well established in Ireland, employment could be created, trades started, manufactures promoted, and the material wealth and comforts of the people increased. These things are at least dawning upon Ireland, and the day is rapidly approaching when she will take her proper place by the side of England as a prosperous country, possessing a happy and a contented people.

Our Dinner.

I don't mean the bit of cold meat we take with us every day, when the shop is a long distance from home, or the beef skirt or Irish stew the missus gets ready by twelve o'clock, when we can go home; but our annual dinner—the bean-feast, or the wayzgoose, as it is sometimes called—which generally comes off about this time of the year, when the governors take a trip with us to the "Rye House" or the "Bald-faced Stag," or some other place where annual dinners are got up in good style for any number from twenty to 200. Those are the sort of places I like. Some shops do the scientific and fashionable, and go to the Crystal Palace, but that don't seem so comfortable like; and as for Brighton, where we went once, I would rather go there in a regular excursion—the ten hours by the sea-side, there and back in a day, for three shillings—than when we have got a dinner, and the governors, and speeches, and all that sort of thing, to think about.

No; I like the steady-going, old-fashioned sort of thing. Vans are not exactly bad things to ride in, only there are rather too many half-way houses on the road, that's a fact; and though it is only the horses who want their mouths rinsed out three or four times in a journey of ten miles, I have noticed that a good many of my mates find it necessary to get out to superintend the operation; and that, when we get to the end of the ride, they are not quite so fresh and clear-headed as they ought to be in the country air. The rail is the best, after all. We only stop at the stations, and there can be no getting out there; and it's of no use Briggs saying to Griggs, "Well, we don't have an outing every day, so what do you say to half a pint, or twopenn'orth cold, on the strength of it—eh, Bill?"

This is how we arrange the business generally: As June comes on, we begin to receive circulars from the landlords of different places, from five to twenty miles from London, where annual dinners are the regular thing. We are invited to come and see the place. There is a cricket-ground, a bowling-green, a skittle-ground, perhaps a stream with boats. If we like to pay 3s. 6d. a head, we can have quarters of lamb, ribs of beef, and legs of mutton, with tarts and cheese, ale and porter; another shilling will give us poultry; and for a crown we can be so aristocratic as to have three courses, salmon and stewed eels coming in before the roast fowls and ducks. Before we decide upon the scale we must see how the funds stand. Of course the governors come down well; some of the best customers make a present, and so do friends of the firm; and we have a little reserve from various shop funds towards the expenses; and then a shilling or two all round settles the matter. Two stewards are chosen, who, some Saturday afternoon, go to Broxbourne, or Upton, or Epping Forest, or Norwood, or Hampstead, or Gravesend, or wherever else we fix on, and look at the place and talk to the landlord, who generally convinces them in a very satisfactory manner that there is no mistake about him, or the quality of the fare he will provide.

So all is settled, and off we go. Saturday is the favourite day, because we most of us feel that such a treat as we are going to have is better for the end than the beginning of a week. The gates of the shop are shut, and a notice, written by the clerk in his best manner, explains that "the establishment is closed for the annual holiday."

We get down to the place about eleven o'clock, and as three is the dinner time, we set to work to play at cricket or bowls, or to have a pull on the water. Some of the lads find out that there are donkeys to be let, and go off for a gallop up the lanes; and the old, steady-going ones sit down and smoke their pipes, and try to persuade themselves that they are quite accustomed to all sorts of rural matters. Our cricketing is pretty good, considering that we are not playing a regular match, and that the best members of our club never can do anything worth mentioning when they have not got their spiked shoes and flannel trousers with them. Some of us, who never touched a bat before, insist on playing, and very funnily we do it. Jenkins goes in, and suddenly finds that everybody is calling out to him to run; so he throws down his bat and runs right across the field, as if a bull were after him. But we are all very jolly, and laugh at such mistakes; and don't we just chaff Brownsmith, who says he has been just having a pull up the river, and ask him how many crabs he caught, and whether they are to be cooked for dinner.

But three o'clock comes, and we all make our way to the big room, where the cloth is laid, and the waiters are already bringing in the dishes. The room does look handsome, and the company to match. We are dressed well, and no mistake. There are at least half a dozen white waistcoats, more than that number silk ones—pattern, large flower on red and blue ground. We are rather bothered what to do with our hats; they are good ones, I can tell you, and drab felts at 6s. 6d. are not to be put anywhere. But that difficulty is got over, and we are all seated; grace is said, and we set to work. Some of the old folks object to the four-pronged forks—left-handed ones, they call them—and others sit as far off the table as they can, turn back their cuffs, and never take their eyes off the boiled beef and carrots. The carving is a little difficulty. We don't like to tackle the fowls in public, for fear of making a mistake, and offer them to each other with the greatest politeness. But we contrive to eat a very good dinner, and when the cloth is removed we settle ourselves to listen to the speech-making.

The senior partner proposes "The Queen," and a private friend of the senior partner's proposes, "Success to the Firm," to which we all respond, making a great noise in doing it, and shouting, "Hip, hip, hurrah!" ever so many times. Then the governor proposes "The Manager," and the manager replies, modestly, from the other end of the table, and we rattle the glasses and shout "Hear, hear;" and one of us ventures to remark that "he's a good sort, he is." The turn of the senior foreman comes next, and he gets up with difficulty, and says he's a man of few words, and isn't accustomed to speaking in public; but he's sure—that is to say, he's been man and boy there for thirty years, and never had a complaint——Then he breaks down altogether, and looks very red and flustered. So we knock the table as hard as we can, and he sits down.

Now we shall hear what speaking is like. Young Wilkins gets up to return thanks on behalf of the men, whose health has been proposed. He belongs to a debating-society, and once addressed an open-air meeting to protest against five gas-works, four vitriol manufactories, three artificial manure works, and seven bone-boiling establishments being set up in the middle of a public pleasure-ground. He did not prevent 400 members of the House of Commons who held shares, protesting that nothing was so conducive to health and enjoyment as the presence of these interesting commercial establishments; but everybody says he spoke out-and-out, and we rather think that now he will show us how the thing ought to be done.

And didn't he just speak! He looked around him and beheld, he said; he saw glorious intellectual progress, he did; labour was going to arise, like something or other, from its ashes;

everybody was to be brother to everybody else; we were all to unfurl banners (which some of us do, being Odd Fellows, and walking in procession); and I don't know what we should have had to do next, for he was getting the steam up, and seemed to be throwing stones at something a long way off, if somebody had not pulled his coat tails, and said, "Cut it, Bob; we'll have the rest outside." So down he sat; and one or two, who believe in Wilkins, said, "That was good, that was; and we wish the Oligarchy had heard him."

Then the governor spoke; and though he did not use such fine words as Bill Wilkins, what he did say seemed to come home to us. He did not speak for more than five minutes; and he said he was glad to meet us all again, and hoped to meet us on many more such occasions; that any employer might be proud of such a respectable, well-conducted body of good workmen; and that he would always be happy to do his best for our comfort and prosperity. Our interests were mutual. We had each duties to perform; and if we discharged them earnestly and sincerely, a confidence and respectful friendship would be established, which was most desirable between masters and men. He wished us and our families health and happiness, and thanked us for our expressions of good feeling towards himself and partners.

We soon afterwards broke up, and got home comfortably. One or two were none the better for the trip, but they were sorry afterwards, and most of us, I am glad to say, set them a better example.

Perpetual Motion.

The discovery of a perpetual motion is a problem which has puzzled the ingenious for more than 2,000 years. We do not mean by it the invention of a machine that will act *for ever*, but one that will continue to move, and even be a source of motion, without the aid of any external agent, until it is gradually worn out in consequence of the natural destructibility of its materials. Perpetual motion, far from being an impossibility in itself, is illustrated by numerous examples on every side of us: for the heavenly bodies are, in the strictest sense, instances of it; since they move at this very moment, by virtue of impulses which they received, it is impossible to say how many thousands or millions of years ago. Indeed, motion is never lost; it is merely transferred from one body to another, or neutralised by union with motion of an opposite kind. But for friction and the resistance of the air, even the machines that we construct would move for ever—but for friction and the resistance of the air! these are simple words, but they express obstacles that never can be overcome. However ingeniously a machine may be devised, or however skilfully constructed, the force which itself consumes *must* be replaced or it will sooner or later cease to move. There is no such thing on earth as perfect smoothness; there is no such thing, therefore, as machinery without friction. All the motion we produce takes place in a resisting medium—even that which is effected in our so-called *vacuum;* and the moving this medium out of our way requires an effort. There are, therefore, two unavoidable destroyers of force always in operation, which will infallibly absorb it, however great it may be; and hence, to keep a machine in motion, we must either act upon it externally—in which case the motion would not be *perpetual*—or we must have recourse to some arrangement of the parts, which is the method adopted. But the very attempt reveals an ignorance of the fundamental laws of mechanics. Since a machine will modify force, but cannot create it, it will enable us, with a certain power, to move a large weight slowly, or a small weight with great velocity; but we cannot by means of it add in the least degree to the amount of motion at our disposal—on the contrary, from the functions of the parts and the resistance of the air, it cannot return to us even as much motion as we impart to it; and, therefore, it is a loss to us to be obliged to use it, however simple it may be. As well might we expect a vessel, from which the fluid is continually flowing, to remain constantly full, as a machine to remain of itself constantly in motion. The machine is to motion what the vessel is to the fluid—a mere receptacle for it. We may withdraw the liquid slowly or suddenly, but the emptying of the vessel is a mere question of time; we may take from a machine the motion we have stored up in it either instantaneously or by the slowest degrees, but sooner or later the whole of it will have been exhausted. The force we impart to a watch or a clock, during the short time we are winding it, is given back in a form more suited to our purpose; but, however long it may go without being wound again, it will stop at last, merely from friction of its parts, and resistance of the medium in which it is placed; and so it must ever be, whatever the mechanism employed.

Those who have attempted the discovery of a perpetual motion have, indeed, sought to attain

Fig. 1.

their object by calling in the aid of gravity, the elasticity of springs, magnetism, &c.; but, however we may conceal it from ourselves, and even from others, by the ingenious complication of our contrivances, gravity will never act unless it has been first overcome; the spring is inert unless it have been previously bent or straightened by force; and a magnet, if in any way it aids us at one time, will to an equal extent oppose us at another. A weight will not move a clock unless it has been first lifted from the ground; and having once fallen, it will act no more until it has been raised again. All that a fallen weight could do, were there neither friction nor resistance of the air, would be to raise a weight equal to itself. Once the spring has regained its normal state, it can produce no further effect until its tension is again violently overcome. In a word, we obtain from machinery only the motion we have imparted to it; and even that, subject to the diminution inseparable from the circumstances in which we are placed. The whole question, then, regarding a perpetual motion, as has been long since shown, resolves itself into that of finding "a weight heavier than itself," or "an elastic force greater than itself."

The search for a *perpetual* motion possesses great fascination for the young and ingenious, but still more to the avaricious, as it is very generally supposed to offer the chance of a large pecuniary prize. This, however, is not the case. No government has promised a reward for its

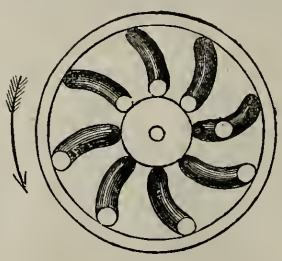

Fig. 2.

discovery; and, at present, any government, or any public body, would be ashamed even to suppose it possible. Nearly a century ago, the Academy of Sciences, at Paris, resolved to receive no communication having reference to it. The attempt to find a perpetual motion is now considered a proof of ignorance and folly rather than a sign of ingenuity; and those who fancy they have discovered it, are invariably ignorant of, or very little acquainted with, even the elements of science.

We may with safety condemn any contrivance of this kind, even unseen; and should not permit ourselves to be led into vain hopes, even by seemingly the best authorities. Apparently respectable testimony as to the *actual* solution of the problem has not been wanting at any period. The Marquis of Worcester, in the fifty-sixth of his celebrated "Century of Inventions," says that a wheel 14 ft. in diameter, with 40 weights, each of 50 lbs., was exhibited in the Tower before the king, foreign ambassadors, members of the nobility, and most of the court; and he appeals to the lieutenant of the Tower, &c., in proof of his assertion, that all persons then present "saw that, no sooner had these great weights passed the diameter line of the lower side, but they hung a foot farther from the centre, nor no sooner passed the diameter line of the upper side, but they hung a foot nearer. Be pleased," says he, "to judge the consequence." Yet this was a contrivance which has been tried a thousand times, and necessarily in vain. In the beginning of the last century, *Orffeyreus's wheel* caused the greatest excitement throughout Europe; and to put an end to the extraordinary infatuation it caused, Desaguliers read a paper before the Royal Society, which is found in the thirty-first volume of their "Transactions." In it he clearly exposes the fallacy of what was believed to be the principle of Orffeyreus's invention. It is scarcely to be wondered that the ignorant were led into error; for it was asserted by those apparently worthy of credit, that this wheel would move *in either direction* if a very slight impulse were given to it; that its velocity would become gradually accelerated, of itself; that this accelerated velocity continued for two months without diminution, during which time it was locked up and carefully sealed in the chamber of the Landgrave of Hesse; and that it was stopped at the end of that period only that it might not be exposed to unnecessary wear. When, however, an eminent man of science attempted to examine it critically, its inventor broke it in pieces, in pretended indignation at an unjustifiable curiosity. But perhaps a yet stronger proof of its not having been in reality what it was represented, is found in the fact that 80,000 crowns were refused for the secret. So recently as 1854, the editor of the American *Journal of Commerce* declares that the model of a machine possessing a "propelling power, *self-contained*, and *self-adjusting*, and having sufficient power to move clockwork without winding up," was exhibited at his office. It was described as starting into motion when the blocks by which it had been stopped were removed. Yet it was only the ordinary arrangement of "arms and balls."

Although the contrivances which have been suggested at various periods for the production of perpetual motion are both extremely numerous and varied, they are all reducible to the same very simple principles, which we proceed to illustrate. It has been attempted to render the force of gravity effective by contrivances which were expected to render one side of a wheel constantly heavier than the opposite; and one of the ways by which it was sought to accomplish this is represented in Fig. 1.

It consists of a wheel, round the circumference of which is arranged a series of rods, movable in one direction by means of joints, which attach one of their extremities to the wheel, and loaded with weights at their other extremities. When the wheel revolves in the direction of the arrow, the rods at one side fall out, so as to become continuations of the radii; and their weights, being then farthest from the centre of motion, produce their greatest effect. The rods at the other side fall downwards; and their weights being then nearest to the centre of motion, produce their least effect. Unfortunately for this and all similar contrivances, it can be shown that the sum of the effects produced by the weights at one side becomes very soon exactly equal to the sum of the effects produced by those at the other; but it will be enough for us to say that, from what we have noticed regarding the nature and uses of machinery, this contrivance *must* soon come to rest, and it has always been found to do so, to the astonishment not less than the disappointment of its numerous inventors.

The next apparatus (Fig. 2) is but a different application of the same principle. It consists of a wheel having grooves or tubes of a curved form, and in each of these grooves or tubes a ball of metal, or a quantity of mercury. When the wheel revolves in the direction of the arrow, the balls, or masses of mercury, at one side recede from the centre of motion, and thus act with their greatest effect; while those at the other

side approach the centre of motion, and thus act with their least effect. One side, therefore, is expected always to preponderate and produce motion; but the objections fatal to the last are fatal to this contrivance also.

Many other ingenious expedients have been used; but the general laws which render *Perpetual Motion* an impossibility, can be shown to be applicable, in one way or another, to them all.

Spinning.

WOOL-SPINNING and weaving have been common in England from very early times, as have flax-spinning and weaving in most flax-growing countries. In Hindostan in the East, and America in the West, cotton seems to have been spun and woven as far back as we have any records of these two countries, in both of which the cotton-plant seems to be a native. Egypt is remarkable as showing the antiquity of flax-spinning and weaving in its native country.

The processes in all these countries were, however, very primitive. The spinning was done chiefly by hand, between the finger and thumb, as one process preparatory to weaving is still to this day, even in our large Lancashire mills. This hand-spinning, though very slow, was very effectual, especially when, as in the case of Hindoo spinners, the sense of touch was highly developed either by native sensibility or by long practice. England could never have competed with India without her present system of machinery. The low price of Indian labour rendered any European competition hopeless, until the wonderful machines, now so common, but none a century old, enabled England to bring her coal and iron to help her to become the spinner and weaver of more than half the world.

Until the invention of the spinning-frame no goods were made entirely of cotton. All textile fabrics are made of two sets of threads interwoven; one running the long way of the cloth, called the *warp*, and the other running across it, called the *weft*. Of these two, the warp should be the stronger; and until cotton could be spun strong enough, the warp was always of linen, cotton being used for the weft only. Under the old English system of spinning by a wheel, or by a distaff, the spinner could not produce thread in sufficient quantity for the weavers, who had thus to spend a part of their time in trying to collect, from house to house, the spun threads as they wanted them; and this difficulty was increased when, in 1738, a weaver named Kay made an improvement in the weaving-loom, by which the process of weaving was much quickened. This improvement was the "fly shuttle," in which the weaver, instead of reaching out his hand to the edge of the cloth every time he had to pass the weft across it, moved the shuttle by means of a double string acting close to his hand in the centre of the loom, by which he could move even two shuttles from right to left and from left to right. Before this invention, it had been necessary, in weaving wide cloth, to have two men, one at either side of the loom.

In the spinning-frame, patented first by Wyatt in 1738, and afterwards by Arkwright in 1768, the cotton (after being opened and cleaned, having its fibres combed out all in one direction, and being carded into rovings) is passed between two pairs of rollers, and is then twisted into yarn by revolving spindles.

The machinery of this "water-twist" machine of Arkwright is somewhat complicated, but its principle may be understood by reference to Fig. 1, showing that portion of it which is directly concerned in the spinning process. The roving was wound up on a large bobbin, and passed from this between two pairs of rollers, B, the second pair of which revolved much faster than the first, by which the roving was made longer and thinner. It then passed to the spindle, D, round which it was wound by the flyer, C, which also, by its revolutions, gave it the necessary twist or spinning. The roving of loose cotton was thus transferred from the bobbin, A, to the spindle, D, being spun during the journey by the flyer, C. The machine was moved by water-power, from which the cotton so spun derived its name of "water-twist." The roving was fixed at the top of the framework, and the spindle and flyer at the lower part of the front; but all the framework and the roving apparatus is removed in the engraving, to make it more simple and more easily understood. The number of spindles was at first some four or six, but was afterwards much increased.

Very nearly at the same time, in 1767, Hargreaves invented another spinning machine, called the spinning-jenny (see Fig. 2), in which a number of reels containing rovings to be spun were placed side by side, and the rovings spun by revolving spindles, without the intervention of rollers; the necessary lengthening of them being attained by a travelling clamp, which rolled backwards and forwards on the framework of the machine.

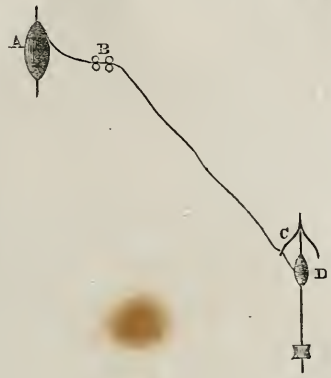

FIG. 1.—PRINCIPLE OF ARKWRIGHT'S SPINNING-FRAME,

In which the rovings passed from the bobbin, A, to the spindle, D. The rollers, B, stretch the rovings, while the flyer, C, revolving round, D, both twists them and winds them on the spindle, D.

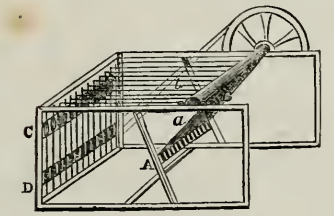

FIG. 2.—OUTLINE OF HARGREAVES' SPINNING-MACHINE.

The rovings pass from the bobbins, A, through the clamp, B, to the spindles, C. The clamp, B, by travelling to and from the spindles, stretches the rovings, while the spindles, C, by revolving, twist the rovings, b, and also wind them up.

In this machine, the rovings to be spun were wound upon bobbins, of which a row was placed side by side in the framework of the "jenny." The rovings passed from the bobbins, A, through the clamp, B, and fastened to the spindles, C. The clamp, B, was then drawn about half way back from the spindles, C, and tightened, so that no more of the rovings could pass through from the bobbins, A. By drawing back the clamp, B, still farther from the spindles, C, the length of roving was stretched longer and thinner; while at the same time, by turning the wheel, which was connected by a band with the reels, D, the spindles were made to revolve rapidly, by which the rovings were twisted into threads. When sufficiently twisted, the clamp, B, was slowly pushed towards the spindles, and the spun threads were wound on the spindles. The clamp was then loosened, more of the rovings drawn through it, and the spinning and winding repeated until the whole of the rovings were spun into thread and wound on the spindles.

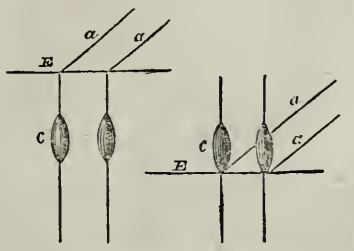

FIG. 3.

Showing how the wire, E, raises and lowers the rovings, to enable the revolving spindles to first spin and then wind them.

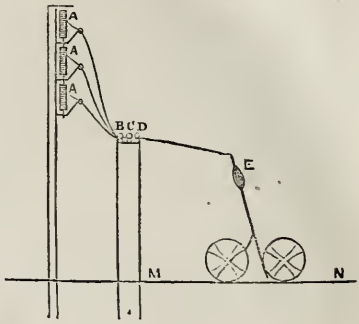

FIG. 4,

Showing the principle of the mule-spinner. The rovings pass from the bobbins, A, to the spindles, E, being spun by the revolutions of the spindles when rolling from M N, and wound by the reverse motion from N to M.

It is especially worthy of notice by what a simple contrivance the same revolving motion of the spindles first spins the thread, and then winds it on the spindles. The same contrivance is still in use in the most modern form of mule-spinner. When being spun, the roving is kept by a wire, E (see Fig. 3), up to the top of the spindle, C, so that the turning round of the spindle only spins the thread; and instead of winding round the spindle, it slips every time over the top of it: but when it is spun, and requires to be wound up, the wire, E, is depressed to the bottom, and then the movement of the spindles ceases to spin the thread and begins to wind it; and by the time the whole spun length is wound, the wire, by gradually rising, has both kept the thread evenly wound over the whole length of the spindle, and brought it once more to the top of it, ready to begin spinning again.

Thus there were two different kinds of spinning-machines brought into operation at about the same time, the one Wyatt's, or Arkwright's, spinning by rollers, and producing a firm, hard thread, fit for warp; and the other, Hargreaves', spinning a finer, softer thread, fit for weft. And now English weavers began to make fabrics entirely of cotton, owing to the improvement in the strength of the yarn enabling it to be used for warp as well as for weft.

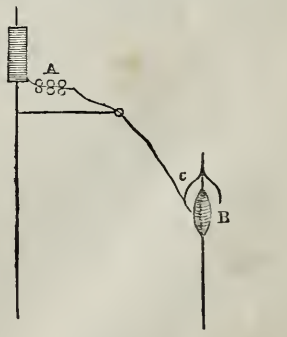

FIG. 5.

Principle of the throstle-spinner, by which the roving, after being stretched by passing through rollers, is spun by flyer, C, which also winds it on spindle, B.

The next improvement in spinning was the invention of the mule-jenny, or mule-spinner, the machine now in general use. This was the invention of Samuel Crompton, a weaver, who

completed it in 1779, after several years' labour. This combines the roller-action of Arkwright's spinning-frame with the spindle-action of Hargreaves' spinning-jenny. The rovings are first passed through rollers, as in the "frame," and then twisted by revolving spindles, as in the "jenny;" except that in the "mule," instead of a movable clamp, the spindles themselves move backwards and forwards, first drawing out and spinning the threads, and then, by the reverse movement, rolling the threads on the spindles.

In a mule-spinner (see Fig. 4) we have the rollers, B C D, moving with different degrees of velocity, and the spindles, E, moving backwards and forwards between M to N. From this combination of the peculiarities of the "frame" and the "jenny" it derives its name of the "mule" spinner.

There is still another spinning-machine, called a "throstle" spinner (see Fig. 5), specially adapted for spinning hard, strong threads, fit for warp.

In this system of spinning, which is not very different in principle from Arkwright's original spinning-frame, the roving passes through the rollers, A, revolving with different velocities, and is then spun by the flyer, C, which, at the same time, winds it on the spindle, B, round which it revolves with great rapidity.

The machines now described were invented more especially for spinning cotton, but they are as applicable to spin flax or wool. Flax is more generally spun by the throstle system, and wool by the mule, and slight differences have to be made in the construction to suit the fibres of each material. It is especially necessary, in all spinning by rollers, that the distance between two pairs of rollers, revolving with different velocities, should not be so little that both pairs can have hold of any one fibre at the same time, for if so, the fibres will be torn in two, and the rovings broken; nor yet too far apart, or the rovings are pretty sure to come in two between them. In flax-spinning the rovings have to be kept damp, to make them more pliable; in wool-spinning the rovings are stretched more than in cotton, on account of the wool-fibres being more elastic.

The process in the manufacture of silk, which corresponds to spinning in the manufacture of cotton, is, properly speaking, called "throwing," though the term "spinning" is sometimes improperly, applied to it. Spinning means the making of one long thread by the twisting together of many short ones; but in silk the only short fibres are pieces left in the working up of the long threads in which silk is spun by the silk-worm. These long threads are put two or more together, and twisted together by machinery, very much like that used for throstle spinning in cotton and flax; that is, it is twisted by the action of flyers rapidly revolving round the spindles on which the silk is to be wound. This process is called "silk-throwing," while the using up of the waste short pieces left, by spinning them into long silk threads, is called silk-spinning.

Club Refreshments.

BY THE REV. H. SOLLY.

It is very important, nay necessary, to bear in mind the distinction between having drink at one's meals and mere tippling for amusement and company's sake at other times. Where there is a dining or supper room in a club, I quite admit that those who wish it should have a glass of beer with their meals, and that they might fairly and safely be accommodated with it without the dangers above referred to arising, provided the rule were strictly adhered to of drawing beer only for those who were having a meal. I am also bound to admit that clubs in the Iron districts, where the men are engaged all day long in work causing excessive thirst, may be in an exceptional condition compared with other such societies; but I confess that, if it should be resolved at the approaching Conference at Oldbury to recommend the introduction of beer into the clubs, I should be far more inclined to yield to the adoption of what one of the delegates called the plan of "Co-operative public-houses" managed by the men themselves, in lieu of the Working Men's Clubs, if both could not be maintained, rather than let the *clubs* become places for the general sale of beer. The Co-operative plan might gradually break the habit of excessive tippling among the older men, and they, or, at all events, the younger men, after a time, might find that they could be just as happy without any beer at all, except what they take at home or at their meals elsewhere; and, therefore, a great deal happier and better in every respect. They would then, probably, form and support a club and institute, with all its higher enjoyments and advantages. If, however, beer should anywhere be introduced I would strongly recommend that it should be drunk only at the bar of the club (unless taken with a meal), and that on no account it should be allowed to be taken into any of the rooms of the club, except the eating-room.

As to what experience says in this matter, let me again quote:—

If, however, these arguments are not convincing, let us see what experience says. I know of only seven clubs where beer has been regularly allowed on the premises. In two of these great disorders, after a little while, prevailed. Dancing, also, was introduced, improper characters obtained admission, and the clubs broke up. In the third there was so little beer drunk that it became sour long before the cask was finished, and proved to be too expensive a luxury. In the fourth, the same process is probably taking place, as the president, a clergyman, informs me that the consumption is only at the rate of half-a-pint per man per week. In the remaining three there are dining-rooms, which, as I said above, puts the matter on quite a different footing. In short, I believe we may say that, if the members are generally steady men, there will be so little drunk that it will soon be nasty enough both to prevent excess and to ensure a loss; while, if they are not steady, their friends need not trouble themselves to form a club for them to drink in, as there are a few beershops in most towns which will probably answer the purpose. Moreover, those men who want their beer at the club, for the sake of attracting and at the risk of injuring whom beer is introduced, and who can't enjoy an hour or two's chat, reading, smoking, or recreation without it, want the *joviality* of the public-house as well as its beer. They will either get this at the club or go back to the tap-room, none the better for having joined the club, but leaving *it* considerably the worse for their brief sojourn there. If they remain, there will be something else wanted before long besides the beer, and that is "a penn'oth of summut short" to put into it. Gin is pretty sure, after a while, to knock for admission where tipplers are patronising beer. It may also be well to consider* that a man who has been drinking rather freely at "a public" may afterwards come to the club, get a finishing pint, make a row, and go home drunk, for which catastrophe, of course, the club would bear the blame; more harm being done to the general character of the club by that one disturbance than mouths of quiet usefulness on its part might suffice to overcome.

Since the above was written, I am bound to state that the Rev. J. Allen, President of the Leicester Club, called upon me, and told me that, so far, the experiment of introducing beer there has been quite successful. Also, that the secretary of the Handsworth Club writes that ale is now allowed there, but limited to two glasses per man each night; *but*, in both cases, the experiment has only just commenced.

I may add to the above the following note, which I received one evening previous to addressing a club in the Midland districts, from which beer was excluded by the rules. It has since been closed:—

Dear Sir,—Will you kindly introduce into your remarks this evening the desirability of members of the club abstaining from introducing into the club intoxicating drinks? Last evening, a party of young men were drinking, making mock sermons, and otherwise conducting themselves in a most disgraceful and disreputable manner. Now, sir, while I, as a member, would like to see all attending happy, I should not like to see this Working Men's Club degenerate into little better than the taverns and singing-saloons which tend to disgrace and degrade all who attend such places. A word spoken in season may do good, and prevent a repetition of such a scene as I witnessed last evening.—I remain, Rev. Sir, yours obediently, A Member.

Allow me to conclude with the observations addressed to the gentleman at Leicester, on the occasion above referred to:—

The plain fact, in short, is that where beer is to be got a class of persons (of both sexes) are attracted, who, by their fault or misfortune, are just the people to damage an institution like a Working Men's Club. It may be taken by many of the members for months without mischief; but by degrees, weaker men suffer, worse men watch their opportunities, and that which without the beer would have been a refuge for some, an elevating influence to others, and a source of rational enjoyment to all, becomes a snare and a nuisance, which good citizens wish they had never promoted, and with disappointment and shame bury out of the way.

These, then, are among the chief arguments that have led so many thousands of the leading supporters of clubs *among working men* to exclude the beer; and I cannot but earnestly hope the members of the forthcoming Conference, as well as of all Clubs in the country, may take that view of the question.

With a sincere prayer that they may be guided to a right conclusion, I leave the matter in better hands than mine.

* Confirming Archdeacon Atterton's remark.

THE MOTHER'S IDOL BROKEN.

There is her nest where in beauty smiled
Our Babe, as we leaned above;
And her pleading face asked for the tenderest place
In all our world of love.
Very silent and empty now! yet we feel
It rock; and a tiny footfall
Comes over the floor in the thrilling night-hush,
And our hearts leap up for the call
Of our puir wee lammie dead and gone;
Our bonnie wee lammie dead and gone.

Last night, with hands to cracking clasp't
In the furnace-fire of my heart,
Sitting, I saw the dead world
All into spirit-life start
At the mystic touch of the white Moonlight.
My spirit arose likewise,
And wandered away to the Graveyard,
Where, a jewel in Death's hand, lies
Our puir wee lammie dead and gone;
Our bonnie wee lammie dead and gone.

Slowly, slowly rose the dead,
All in their robes of white!
Weirdly, weirdly rose the dead,
All in the silent night!
Like lilies for God, from the dark grave-bed,
They grew in a glory-rain;
And the crowned Darling of Heaven, at the head
Of all that glorified train,
Was our puir wee lammie dead and gone;
Our bonnie wee lammie dead and gone.

In my dream I stood at the death-door dark,
Alone and tremblingly,
Till a Shining One came in a crescent bark,
Moonlike, o'er a purple sea.
She smiled as to say she knew the way,
And at some secret sign,
A memory of the old life stirred,
And I knew that Angel mine!
Our puir wee lammie dead and gone;
Our bonnie wee lammie dead and gone.

—*From "Craigcrook Castle," by Gerald Massey.*

THE CAMBRIDGE FREE LIBRARY.

This useful institution is situate under the Guildhall, and is most extensively patronised by those for whose use it was principally intended. The Library Committee consists one-half of members of the Corporation, and the other half of inhabitants of the town and university. This plan has been productive of the greatest benefit to the institution. The annual allowance from the Borough Fund is £300 (or not quite a ¾d. rate), and no rent is charged for the use of the rooms. The rooms occupied are spacious and well lighted, the size of the reading-room being 45 feet by 42, and that of the library 42 by 25. There are separate entrances to the library and reading-room. The reading-room is open from 11 a.m. till 10 p.m. daily, and is supplied by 13 daily and 15 weekly newspapers, 35 weekly, fortnightly, monthly, and quarterly magazines. In addition there are 370 volumes of books of reference and other works of general interest kept in the room for readers to obtain readily as they are required. The library consists of nearly 12,000 volumes, about two-thirds of which have been presented. The late Prince Consort was a donor of 140 volumes, of the value of £50; and the late Dr. Whewell was one of its first contributors. The principal donor has been Mr. James Reynolds, who has contributed nearly 2,600 volumes, and next to him may be mentioned Mr. H. T. Hall (a member of the Council), who has presented about 650 volumes. Last year, G. E. Foster, Esq., contributed 134 volumes, of the value of £50. The issue of books has continued to increase from year to year, but this year there will be a decrease, resulting from the fact that no catalogues of the new books that have been added to the library have this year been published. Last year the circulation was 44,435 volumes. The lending library is open daily, from 11 a.m. till 2 p.m., and from 6 till 9 p.m. One feature of the Cambridge Free Library is the collection of books, pamphlets, and other documents having reference to local affairs. The collection of old prints and views of the colleges and public buildings are many of them rare, some of which are framed, and cover the walls of the reading-room, and prove a source of much interest, as also do the portraits of local celebrities.

THE VINE.

IN Miss Elizabeth Twining's interesting and instructive work, "The Plant World," we find the following account of the vine :—

"The grape-vine ranks highest in the class of fruit-trees; it was among the earliest known to man, and the art of making wine was one of the first discoveries of the uses of those trees yielding fruit which were given to him 'upon the face of all the earth.' The vine, like some other plants we have studied, has a certain region of the world marked out for it. The tropics will not do for it, neither the cool climates of countries that are situated beyond the fiftieth degree of latitude on the north; therefore, the vine cannot grow in the open air, except in peculiarly favourable spots or sheltered places, in our country, neither in the north of France nor Germany. In entering France on the north, we see no extensive vineyards until we have travelled beyond Paris southward, or into the warm provinces to the east in the old territories of Champagne and Lorraine. The vine flourishes also in the north of Africa nearly in the same tract of temperature as that of maize. But in Central Africa no vines will be found; it is too hot and scorching throughout the tropics of that continent; when the climate cools a little beyond that limit at the Cape of Good Hope, the vine is again cultivated, and much good wine is made and sent to other countries as Cape wine. The vine grows wild about the southern shores of the Caspian Sea at the present time, just in that part of Asia which was first inhabited by the human race. From thence it followed the course of population and civilisation; wherever man progressed and cultivated land, there vineyards were planted.

"It is very curious to trace the advance of the vine; from Asia it was brought into Greece—a country famed for the wisdom and learning of its people for many centuries. Thence it was taken to Sicily, and cultivated there in great perfection. As the Romans took possession of new countries in Europe beyond their own Italy, they introduced the art of planting vineyards, and those which now cover the sloping hills on the banks of the Rhine and the Moselle in Germany, are said to have been originally planted by the Romans when they were established in that country. In ancient records of the time when the Saxons became rulers in this land, there are accounts of vineyards, which seem to prove that the Romans had, in the course of their 400 years of dominion, taught the people the way to plant vines and to make wine. At that time the climate of England was much warmer than it is now, and the cultivation gradually diminished after the produce of more southern countries increased sufficiently to supply us. When the farmers learned how to cultivate their land with various crops, and the monasteries were broken up, it was found better to grow corn than vines. About 300 years ago only a few vineyards in favourable situations in the southern counties were still to be seen. It was not until the beginning of the last century that artificial means were adopted to ripen grapes; the vines were then planted and trained against a wall, on the other side of which fires were made. About 100 years ago the first houses covered with glass were made for vines. In these hothouses grapes ripen well, and are thought to be as rich and well-flavoured as those which grow in the open air in more natural heat. It is probable, however, that they do not acquire some of their best properties so fully.

"We have already observed the tract of the earth's surface on which palms and also corn flourish best; you can now trace out on the map the region of vines. It spreads over nearly 2,000 miles in breadth on the north of the equator, including the north of Africa and south Europe. The best part of this region is Spain and Portugal, where the choicest kinds of grapes ripen well, and are made into excellent wine. Even there the climate varies in its suitability, and those grapes which grow in the southern provinces are chiefly fit to be dried as raisins in the sun. In some districts the grapes must be steeped in a preparation before they are exposed to the sun for drying. This causes some difference in the quality, and is the reason why Malaga raisins are preferred for some purposes and those of Valencia for others.

"Vines have a trailing stem that is unable to support itself without some kind of prop, but if that be given, they climb over it readily, clinging on firmly by means of the curling tendrils on the branches. The most ancient manner of training vines was upon other trees, and this is still preserved in Italy. One of the striking parts of the scene to a traveller descending the Alps into the plains of Lombardy, is the sight of vines trained to peach-trees in the open fields, their branches forming festoons from one tree to another, laden with purple grapes, if it chance to be in autumn.

"In some hot countries of the East, the primitive custom of planting vines by a well, and training them over a trellis-frame, is still maintained, and the owner and his family repose and refresh themselves under the pleasant shade. This explains the similitude used by the patriarch Jacob when, blessing his sons, he likened Joseph to 'a fruitful bough by a well.' When the fruit is ripe, it is gathered into carts and taken home. The very choicest wine—as that of Tokay in Hungary—is the first dropping of the rich juice before the grapes have been pressed. The ancient treading of the wine-press is referred to so often in the Bible, that we know it must have been a national custom. It still remains the common way of obtaining the juice in many Eastern countries, and in Italy it is the usual practice, although in some vine districts a kind of press is used. In Spain, goatskins are dried and sewed up into bags to keep wine in; which recalls to mind the illustration used by Christ to his disciples, about putting 'new wine into new bottles,' lest the wine be spilled. The skins were liable to crack and burst when old, but a glass bottle remains secure until it be accidently broken.

"Concerning the region of the vine in the East Indies, we must remark that it does not extend in the same latitude as in Europe, on account of the different kind of temperature. The French, when they took possession of Pondicherry on the east coast of Coromandel, in twelve degrees of latitude, established vineyards there. In the north-west provinces of Asia the vine thrives well, but, in general, the grapes do not make good wine, nor can they be dried as raisins. In some parts of the Himalaya, grapes ripen at an elevation of 9,000, or even 10,000 feet, and are converted into wine and raisins. The vines of the luxuriant valley of Cashmere find a suitable temperature at 5,500 feet. In China and Java, also, vines are cultivated. In the New World, there is, likewise, a region of vines gradually extending, according to the progress of civilisation and the art of culture. On the Andes, vines are generally found to thrive where the maize can grow, up to an elevation of 7,000 feet above the plains. From America vines have been transported to the Sandwich and other isles of the Pacific Ocean, whilst from England they have been carried to, and successfully planted in, Australia. All this seems to be an indication of that future time dawning, which the prophet foresaw 2,560 years ago, when peace shall prevail over the earth; when spears shall be beaten into pruning-hooks, and 'nation shall not lift up a sword against nation, but they shall sit every man under his vine.' Young vine plants begin to yield fruit at two years, and are said to improve in quality until fifty years old. Their duration is extreme; for in France and Italy there are now vineyards in existence, which are known to have been in full vigour for at least three centuries.

"The learned naturalist Pliny, of whom I have before told you, mentions a vine which he had seen when it was 600 years old. The stem attains a considerable size when all circumstances favour its growth. It is said in an ancient book that two men could not embrace one, which far surpasses the usual size. When the wood is old and compact, furniture is sometimes made of it, and much esteemed for its durability.

"The small black grape from the vine of Ascalon and Zante, formerly chiefly cultivated in Corinth, has no seeds: this kind is dried for use, and is well known in this country as dried *currants*. You can now easily perceive they cannot be real currants, such as we have on currant bushes in our gardens; because you learned in the chapter on *fruits* that they have the remains of the withered blossom on the top of the berry, but the grape is placed entirely above the flower, therefore is smooth, and shows no trace of calyx or petals. A larger white grape, also without seeds, is, when dried, the kind we call Sultana raisins. Even this one trifling production of the vine tribe is become an important article of commerce in the present populous state of the world. Upwards of 100,000 hundredweight are sent here annually from Spain; a still larger quantity come from Turkey, and a considerable portion, also, from Italy. Raisins are used in various ways for cakes of all sorts and for puddings. Wine is also prepared from raisins as well as from grapes in their fresh state, and is of excellent quality, preserving its strength and goodness for many years. The fruit is almost equally nourishing and refreshing in its dried state, as when fresh gathered from the vine. There is very early record of raisins being eaten as food, and affording really strengthening sustenance. When David was at war with the Amalekites, the Egyptian who was found fainting in the field was revived by the food given him, part of which was 'two clusters of raisins.' Then we read of a present being made to David, one portion of it being 100 bunches of raisins. And when, by general consent, David was made king at Hebron, and 'there was joy in Israel,' amongst the things which composed the gifts for the feast, were 'bunches of raisins.'

"The seeds of grapes contain a very pure oil, of the same nature as that of the olive. The leaves and tendrils have a peculiar astringent taste, not at all perceptible in the ripe fruit, which has completed the work which the leaves begin, of converting all the juices of the plant to the formation and perfection of the fruit."

GUTTA-PERCHA CEMENT.—A good gutta-percha cement is made by dissolving gutta-percha in chloroform in quantity to make a fluid of honey-like consistence. When spread it will dry in a few moments. Heat the surfaces at a fire or gas flame until softened, and apply them together. Small patches of leather can be thus cemented on boots, &c., so as almost to defy detection, and some shoemakers employ it with great success for this purpose. It is waterproof, and will answer almost anywhere unless exposed to heat, which softens it.

Facts and Memoranda.

SEVEN hundred thousand tons of soda, worth about five millions sterling, are annually consumed in England.

M. CHEVREUL states that mutton tallow contains twenty-nine separate substances, amongst which are a number of acids. The majority are united with potash, some with ammonia, lime, magnesia, oxides of iron, manganese, and copper.

THE Council of the Central Cottage Improvement Society having offered a premium for the best design for a detached cottage for labourers, have received upwards of 100 designs, which, in a few days, will be exhibited at the rooms of the Society of Arts, Adelphi.

HOW TO PRODUCE COLD.—Dr. Phipson has found that when 207 parts of lead, 118 of tin, 284 of bismuth, and 1,617 of mercury, are mixed together, the air being at the temperature of + 17° Centigrade, the temperature of the mixture falls to — 10° Centigrade. The mercury in such a mixture being readily recoverable for use over again by distillation, Dr. Phipson is of opinion that the production of cold by this method is susceptible of numerous useful applications.

A MONSTER BRIDGE.—The monster bridge, the largest constructed on the Lewisham and Tunbridge line of railway, and which is built over the road leading from Green Street Green to the above village, contains nearly three millions of bricks. That quantity placed lengthways would reach from Orpington, in Kent, to the city of Glasgow, in Scotland, a distance, by the old turnpike road, of 426 miles; or the same quantity of bricks would pave fifteen acres fifty-nine perches of pasture land.

AN ENDURING BEAM.—Some days ago, in demolishing a portion of the Paris *Cité* for the site of the Hôtel-Dieu, the workmen discovered an oaken beam in one of the most ancient houses, which had a section of 1·36 mètre. There was very little sign of decay, and on one of the sides was the following inscription:—"I was placed here in the year 1450, and was 600 years old when I was taken from the forest of Bovray, of which the Bois de Boulogne is a small portion." Nearly a contemporary of Charlemagne!

CARBOLIC ACID.—The antiseptic properties of carbolic acid are supposed by some to have been only recently discovered; but the fact is, that, from time immemorial, carbolic acid, creosote, or bodies containing them, have been used as antiseptics. Passages in Pliny, read by the light of chemical science, show that the Egyptians used for embalming their mummies a compound made from pitch, which must have contained large quantities of creosote. Carbolic acid is the active agent in tar, which, either in its ordinary state or burnt as a fumigator, has always held high rank amongst disinfectants.

A NOTEWORTHY fact in connection with the present difficulties on the Continent is, that all countries likely to be engaged in the war have increased their supply of coal to an enormous extent. Italy has been importing coal lately in such large quantities that the freights on the east coast have greatly advanced, and vessels can scarcely take the coal with sufficient rapidity. This supply is for the Italian navy. Austria has also increased her supply of coal very largely, although it would appear that her navy is not to be actively engaged in acts of aggression upon Italian merchantmen. Prussia has also largely increased her supply, and the same remark will apply to Russia and France.

PATENT SAFETY GAS-TAP.—The absence of a safeguard to prevent the accidental turning on of the tap, which often arises by an undesigned knock whilst dusting or cleaning the gas candelabra or other fittings, causes many fires, explosions, and other disastrous accidents; as also does the want of a protection against children or others from improperly turning on the gas. A patent safety gas-tap has been invented which renders the accidental turning of the T piece impossible, by means of a very simple and cheap addition to the ordinary gas-tap. A small spring is so arranged, that by the action of the fingers in turning the T piece or plug, it is readily depressed, and then freely allows the gas to be turned on, whereas it effectually secures the gas-tap from being opened by any accidental cause. If not liable to get out of order—and there seems little fear of that—this invention must greatly tend to ensure safety in the use of gas. It can be applied, at a very trifling cost, to existing gas-fittings, and is readily applicable to the ordinary gas-taps.

A NEW LIGHT.—Professor Carelvaris, of Genoa, has invented a new light, called the Carlevaris light, and the experiments made at the close of last month in the theatre of the Technical Institution were attended with great success and loudly applauded. This light is an oxy-hydro-magnesian flame, and is obtained by placing in the flame of a mixture of hydrogen, or coal gas, with air or oxygen, spongy magnesia, a substance of very small cost. The flame is white, rich in actinic force, fixed, and developing less heat than other lights. The expense is very trifling, a light equal to four wax candles only costing two-tenths of a penny per hour. A new trial also took place in the lantern of the Genoa lighthouse. It proved that this light was superior to that of the oil-lamps representing an illuminating power of twenty-three Carcel lamps, and yet the cost was only 3d. per hour.

"ALL LABOUR IS SACRED."—*Carlyle.*

THE WORKING MAN.

JUNE 23, 1866.

Erratum.—The author of the article headed "Co-operation and the Journeymen Bakers," in No. 23, has called our attention to an error of the press, by which a passage in it is left open to a construction conveying an imputation on the journeymen bakers of Ireland. We hasten to acknowledge the mistake, as nothing could be farther from our intention than to reflect on so orderly a body as we have every reason to believe them to be.

A Penny Series.

We believe that the Working Man, the first volume of which will be concluded in our next number, has been the first periodical established with the double purpose of supplying instruction to the artisan and information to the citizen. During the progress of this Journal no pains have been spared, either as respects illustrations or matter, to make it an acceptable representative of the useful classes: and we are gratified to find that the general opinion of the public is appreciative of these endeavours; and only one wish is expressed—namely, that as respects price—that the utility of this Journal could be extended to a yet larger circle of readers; and we have resolved to meet this wish by making the price of the Working Man, on the issue of No. 1 of our second volume, One Penny. We have reason to believe that we may rely upon the interest of our readers to promote the success of the undertaking.

Not only will the illustrations and features of special approval be continued, but we hope to add others, which shall have further value. Quite apart from party politics, we shall discuss political as well as social questions, from a national point of view, and with regard to their bearing upon the large class of whose interests the Working Man claims to be the public representative. We take the title Working Man in that nobler sense expressed by Carlyle, in his memorable phrase, "All labour is sacred." We include under that phrase all those who gain their income by active exertion in every pursuit in life.

Our desire is to create a paper which shall have not only a weekly but also a permanent interest to working men—one that shall be necessary not only to the workshop, but also to the families of the industrious classes; welcome to the news-room, and to all who wish to see the views of working men on industrial, social, and public questions.

Lodging-House Legislation.

It is a question often raised, what amount of air a person requires to breathe and continue well. Of course, it depends upon many circumstances—health, age, and exercise influence the degree of want felt for it. Incidental light is thrown upon the subject in two quarters very remote from each other, whose proceedings have in one case come, and in the other will come, before the public.

At the official inquiry into the condition of the Strand Union Infirmary, the doctor told the commissioner that he wanted 1,000 feet of air for each patient, being half the allowance at the Fever Hospital and day-rooms for the infirm. From which we learn that 2,000 feet are deemed necessary at these places for diseased and aged persons.

At a conference of chairmen, vice-chairmen, and other officers of local boards of Newcastle-on-Tyne and neighbouring towns, held at Lieutenant-Colonel Potter's offices, Willington Quay, a resolution was proposed that Parliament should be asked to enact that no person shall be permitted to take lodgers unless his house contains 250 cubic feet for every adult member of the landlord's family, and 125 cubic feet for each member of the landlord's family under eight; and after such amount, 300 cubic feet for each adult lodger, and 150 feet for every lodger under eight; and that a family shall be held to consist only of the landlord's family in the first degree, as a father, mother, and children, or a family consisting of brothers and sisters exclusively; all other persons being considered as lodgers.

No doubt this proposed enactment points to the minimum quantity of air necessary to prevent overcrowding and the generation of fevers. Such a rule would prevent ignorant or needy landlords from taking into their houses more persons than could sleep with a decent chance of health. The number of persons whom any landlord would be permitted to house, would be determined by his sleeping-space, measured in cubic feet. This is, no doubt, a merciful regulation, which those local Boards seek to enforce. But it naturally occurs to one, that when provision is thus made for the quantity of air, some obligation ought to be imposed upon the landlord to provide for its change. Air, to be breathable, must be fresh. There is no enactment even thought of as yet to compel ventilation. This omission, at present, must be tolerated. It is something to see Parliamentary attention directed to securing the quantity of air which every human being ought to be secure of finding in every lodging-house. Provisions for ventilation will follow, doubtless, in due course.

Now and then an ill-timed strike takes place. Dictated by passion as often as by prudence, a strike will often be ill-advised. Such a one appears to have occurred at Ottery St. Mary, in Devonshire, according to newspaper reports. We have not as yet seen the men's case stated. The side which has been stated represents that a portion of the town has been destroyed by fire, and that a public subscription of £3,000 has been generously made to aid the poor people burnt out. At this juncture of affairs the workmen there turn out for an advance of wages, and advertise a warning that no carpenters or bricklayers need apply there, as the resident operatives are out on strike. We have no doubt these working men would be as ready as any other classes to remedy a public calamity. Their strike may be based on a conviction that the contractors are profiting by the subscriptions supplied, and think themselves entitled to share in them. We should think they must have some palliating reason. Unless they have a very strong one, they must be held to be open to grave censure. Under any conceivable circumstances, it seems an ill-timed strike.

The discussions on coal which have of late occupied the attention of the House of Commons, are likely to affect working men sooner than was to be anticipated. We do not expect any sudden scarcity, but there will be a rise in price, and that before long, unless the question assumes a better aspect. Very experienced coal-owners really think, with Sir William Armstrong, that scarcity will occur early; others believe with Mr. Hussey Vivian—who made a dull, subterranean speech the other night in Parliament upon the subject—that we have more coal than is imagined; that it can be got at a greater depth than is supposed, and that we may economise its use, as Sir William Armstrong proved, saving seven-tenths of it, if we remember the proportion rightly. In the meantime the Budget speech of Mr. Gladstone, in which he referred to the probable day of scarcity, has had its effect on coal-mine proprietors. Two gentlemen were mentioned last week in conversation at the House of Commons by two northern members, who had agreed to let land for mining purposes, at a certain royalty—that is, a tax of so much per ton, to be paid by the getter—and now they demand a double royalty. The effect of this will be that the price of coal will be raised, and the poor consumer will feel the effects of the coal debates; and coal enters into the cost of manufactures so largely, that many articles of use will be raised too, if ever the price of coal is substantially increased.

A gentleman who has written himself into reputation, and whose reputation is likely to depend more on his pen than his tongue—we mean Mr. Kinglake—made a speech in Parliament on Tuesday night, on the impending war. In the course of it he represented that Italy was gratuitously seeking occasion of war with Austria, and that, "in the event of a war between Austria and Italy, it would be a war without a quarrel." This is disguised language, seeing that Italy has had deadly cause of "quarrel" with Austria from the day in which it began its brutal rule in Venetia. The same speaker afterwards spoke of Venetia as being "rather more Italian than Austrian." "Rather more!" This is a wonderful phrase in an assembly which piques itself on language of exact truth. Mr. Howells, an American consul, who was occupied with official duties in Venice for three years, has just published the results of his experience. He states that so intense is the Venetian hatred of the Austrian, that a predecessor of his who spoke German was always distrusted; that an Italian man or woman who speaks to an Austrian, is shunned by

their own countrymen and women. No Italian lady will suffer an Austrian, nor any one who knows an Austrian, to enter her house. The Italians will not meet in the same *café* to eat, nor in the same church to worship, with Austrians. They will not stand in the same square where Austrians are, even to hear music, of which Italians are so fond. They will not go to any theatre where an Austrian enters, and they have for long years abandoned their national festivals, rather than Austrians shall share the pleasure, or even witness them in moments when they may seem to forget their hatred. This is what Mr. Kinglake describes as being "rather more" Italian than Austrian in sentiment.

DIPLOMACY has broken down under Bismarck. The enterprising Count, who has a European reputation for political intrepidity, has just addressed a despatch to the Prussian representatives abroad remarkable for its employment of language the opposite of that for which diplomacy was invented. Not content with dissenting from Austria, the Count speaks of the Emperor as having a "theoretical love of peace," and an actual "craving for war which dominates over him." This language might pass for a vigorous description of Imperial psychology, but the enterprising diplomatist takes upon himself to say that "expressions of influential Austrian statesmen and councillors of the Emperor have been reported to the King from an authentic source, which leave no doubt that the Imperial Ministers desire war at any price, partly in the hope of successes in the field, partly to tide over domestic difficulties—nay, even with the expressed intention of assisting the Austrian finances by Prussian contributions or by an 'honourable' bankruptcy." Diplomatists profess to confine themselves to statements made in official documents duly accredited; but here the Count brings in "expressions" of irresponsible individuals who speak unofficially. Anything can be proved, and anybody may be assailed, on this plan. Found accusations on all a man's friends or acquaintances may say, and no one would be safe, and quarrels would never end. The Count makes use of these private "expressions" to found his charge, which no official document would enable him to do, namely, that the Imperial Ministers of Austria "desire war at any price"—that they seek conquest—have private ends to meet—intend plunder and bankruptcy. Such is the meaning of "hope of successes," "domestic difficulties," "assisting Austrian finances by Prussian contributions," with a view to "honourable" scheduling. Diplomacy professedly deals with facts and principles, and avoids imputation, which proves nothing, and retards and embitters everything.

WOMEN are finding their way into Parliament earlier than was expected. The other day they brought a petition to the House of Commons. Two ladies attended with it, in a cab, and presented themselves (not the cab) in the lobby of the House in search of a member to present their petition. When ladies come "lobbying," what will become of honourable members? The petition, signed by 1,500 women, was drawn with singular good sense and good taste. It set forth that it is constitutional for women to meddle with politics. A woman may reign: she is eligible to public offices. All holders of property are allowed electoral rights; why, then, should women, one part of the nation holding property, be excluded from a right presumed to be common to all? These are fair questions. Mr. J. S. Mill has moved for a return of the number of women who possess electoral qualifications—who are householders, and pay rates—but are excluded from the right of voting on the ground of their sex. Strange as it may seem, it will not be possible much longer to exclude the women who hold property and pay rates from the rights common to all other persons fulfilling only the same electoral conditions. The *Spectator* cites the proceedings of certain ladies who held a Congress in New York, and who made some absurd speeches, as an instance of the unfitness of women to partake of political power. The objection is futile. Many men are quite as absurd as any women when new to political life. When women are once permitted to take part in public affairs, they will soon learn to do so temperately and well. On this point the usually sensible *Spectator* talks very much like Lord Macaulay's fool, who held that nobody should be allowed to go into the water until he had learned to swim. Women, like men, will acquire political lessons if once allowed to enter the political school, where alone the lessons can be learned.

WHEN a murder has been committed, somebody must be hanged to keep up the credit of the police. This is an unfortunate expectation. The last mysterious London murder of Sarah Millson in Cannon Street has nearly been followed by one not mysterious, but open and yet more dreadful, because the judicial murder of an innocent man. William Smith, the Eton journeyman hatter, was charged with the murder. Idle, dissolute, and of doubtful character, all these bad qualities told against him, and gave probability to a charge also supported by his evident transactions with the murdered woman. Eton is fortunately a place where the residence of a murderer would be what the Scotch would call a "felt scandal," and William Smith's case was looked into by persons who were intelligent, or who knew persons who were, and the allegations against Smith were sifted and confuted; so that, when the jury declared him not guilty, Baron Bramwell added, "It is due to the prisoner to say that he was more than not guilty—he was innocent." The question then arises, How came the man to be put upon his trial at all? By taking the wrong man, and putting his case before the country, the real murderer was relieved of all uneasiness as to his safety. It is quite time that public prosecutors, responsible and intelligent, were appointed. How can it be expected that policemen, not over-paid, and chosen for courage and detective activity rather than judicial knowledge, can discharge properly the serious function of bringing deadly charges at will against members of the public? A person once charged is half condemned. It is a very difficult thing to get any exculpatory evidence heard. A poor man can hardly hope to escape, unless he has intelligent friends who will spend money on his behalf. Censured as the police naturally are when a murderer escapes, they feel a professional desire to hang somebody; and the temptation to do this ought to be taken out of their way. Had not William Smith had the good fortune to reside at Eton, we greatly fear he would have been hanged.

The Workmen's Exhibition Prize Medal.

WE are enabled this week to give an illustration of the prize medal which has been designed by Messrs. J. S. and A. B. Wyon for the forthcoming Metropolitan and Provincial Working Classes' Industrial Exhibition. The design is entirely original, and is in perfect keeping with the object for which the medal will be struck. The period for opening the exhibition is now definitely fixed for the 3rd of September next, and all applications for space must be sent in on or before the 30th of June. In addition to the medal, money prizes, amounting in all to about £75, have been offered by gentlemen who are desirous of encouraging workmen exhibitors, and this will no doubt have the effect of increasing the interest of the competition. It is to be hoped that the council will obtain the assistance of competent judges to award the prizes, in order to avoid the expressions of dissatisfaction which have resulted on more than one occasion from a disregard of this necessary element of management.

THE WORKMEN'S EXHIBITION MEDAL.

Our readers are already aware that one of the silver medals is to be presented to the collector of the largest sum towards the WORKING MAN LIFEBOAT FUND, subscription forms for which may be obtained on application by post to our office.

Mechanical Properties of Matter.

BY THE REV. PROFESSOR HAUGHTON, M.D., TRINITY COLLEGE, DUBLIN.

THE whole science of mechanics consists in the investigation of the three following subjects:—

I. The sources and nature of the forces employed.

II. The instruments used in applying these forces to the resistances to be overcome.

III. The nature of the resistances themselves.

We shall find it convenient to investigate these subjects in an inverse order, and shall, therefore, commence with a description of the fundamental mechanical properties of matter, on which its resistance to the application of force entirely depends.

All the bodies in nature, with the exception of oxygen, hydrogen, and nitrogen, are capable of existing in three distinct conditions, as gases, liquids, and solids; and there is reason to believe that oxygen, hydrogen, and nitrogen, which are known to us only as permanent gases, might be forced to assume the liquid and solid forms like other bodies, if we had at our disposal the requisite mechanical means for their reduction.

At a given temperature of heat, and under given conditions of mechanical pressure, a body may be a solid; if the temperature be raised, or the pressure diminished, it will become a liquid; and

under a further rise of temperature or reduction of pressure, the same body will exist as a gas or vapour. Hence it follows that in a state of nature—that is, under given conditions of atmospherical pressure and temperature—some bodies are naturally solid, as limestone, copper, &c.; others are naturally liquid, as mercury, brandy, &c.; and others naturally and permanently gaseous, as air, hydrogen, &c.; while a body such as water is, in these and higher latitudes, placed under such conditions as to temperature, that it is sometimes liquid water and sometimes solid ice.

Solids.—There is no definite or absolute quality which constitutes a solid, although they all agree in more or less resisting the intrusion of another body. We can plunge the finger without difficulty into a vessel filled with milk or water, but we cannot do so with stones, wood, metals, and ordinary solids; yet we have no difficulty in thrusting the finger into a mass of dough or mortar, which are substances belonging to the border-land between solids and liquids, and may be referred, without impropriety, to either of these classes.

Some solids are *hard* and *brittle*, as glass, marble, tempered steel, &c.; others are *soft* and *ductile*, as butter, clay, lead, gold, copper, iron, &c.; and such ductile bodies, if metallic, are also *malleable*. The ductility and malleability of some metals are of the greatest importance in the arts, and depend essentially on the power possessed by these bodies of changing their shape in an infinity of ways without rupture or breach of continuity. Silver, gold, and platinum are the metals that possess these remarkable qualities in a high degree.

The following experiment was made by Dr. Wollaston, to illustrate the extraordinary ductility of platinum. A wire of platinum $\frac{1}{700}$th of an inch in thickness, coated with silver $\frac{1}{5}$th of an inch in thickness, was drawn out as long as possible without rupture, and the coating of silver carefully removed with the aid of boiling nitric acid; it was found, on trial, that 3,000 ft. in length weighed only 1 gr., and that a single silkworm's thread possessed a thickness equal to 140 such threads of platinum. Now, as each foot contains 144 lines, and as the $\frac{1}{10}$th of a line is readily visible to the naked eye, it follows that a single grain of platinum can be divided into 4,320,000 parts, each of which is distinctly visible.

Gold is scarcely less ductile than platinum, for it has been proved that the gilding of the thread used in gold embroidery is reduced to plates of less than $\frac{1}{50000}$th of a line in thickness.

Some very interesting experiments have been recently made by M. Tresca on the behaviour of ductile solids when squeezed through various apertures, and the tendency of his results is to show that solid bodies of all kinds, when a pressure sufficiently intense is exerted upon them, flow in a manner precisely similar to liquids. The same phenomena were proved to exist for the soft as for the hard metals; for plastic substances, such as blocks of wax; for pulverulent matter; for granulated materials, such as musket-shot, and in a manner only less complete than in the case of the liquids themselves.

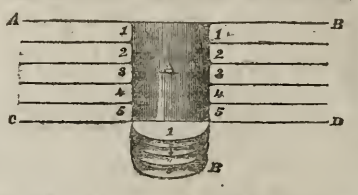
When a number of plates of lead or iron are superimposed on each other, and punched out in a direction at right angles to their surface, very interesting and important results are obtained from an examination of the "burr" forced through the plates. Let us suppose five plates superposed, as in the annexed engraving, in which A represents the cavity formed by the punch, which is flat-headed, and not allowed to pass farther than the level, C D, of the lowest plate. An examination of the "burr" B, by means of a cross section, discloses the following curious facts:—

1. The total volume of B is less than half that of A, although the density of B is not sensibly greater than that of the original plates.

2. The first and last two plates appear in the "burr" of nearly their original thickness, and the loss of substance affects principally the central plates.

3. The plates 1, 2, 3, 4, 5 in the "burr" are *continuous* with the plates 1, 2, 3, 4, 5 in the original series; so that the "burr" is formed of a number of thin shells of metal piled one over the other like so many hats.

I take the following numerical example from M. Tresca's memoir, as an illustration of the relation between the thicknesses of the plates punched through to form the complex "burr." The unit of thickness employed is the millimètre, which is 0·03937 of an English inch. Sixteen plates of lead, each 4 millimètres thick, were carefully placed over each other between two holding plates, each pierced with a hole of 20 millimètres,



to allow the punch to pass through. The force of a hydrostatic press was employed to push the punch through the entire series of sixteen lead plates, the metal of which in front of the punch formed a cylinder of 20 millimètres diameter and 64 millimètres in height. When the burr was completely pushed through, it formed a cylindrical solid of 20 millimètres diameter, but had a total height of only 31 millimètres, less than half its original height, which was 64 millimètres. On cutting the burr in two, and smoothing over the cut faces, the fifteen lines, showing the number of divisions in the primitive block, were visible; but while the first and last three plates were represented of their original thickness of 4 millimètres or rather more, the intermediate plates were considerably reduced in thickness, as may be seen from an inspection of the following table, which gives the thickness of each plate measured in the burr, together with its gain or loss above or below the original thickness of 4 millimètres of the plate from which it was derived. It will be seen from the results that a flow of lead must have taken place *from* the plates 2, 3 . . . 12, 13, into the surrounding metal.

TABLE SHOWING THE THICKNESS OF SIXTEEN PLATES OF LEAD, ORIGINALLY OF 4 MILLIMETRES EACH, PUNCHED INTO A BURR.

THE RATE OF MECHANICS' WAGES IN ENGLAND AND ON THE CONTINENT.

An article which recently appeared in the *Engineer* on the above subject has drawn forth a reply from an "Old Reader," and a "British Workman" to boot, who writes from Grünwald Reichenberg, Bohemia, under date of June 3rd. We give the letter almost entire, feeling assured that it will be interesting to many of our readers.

"From what I can understand, the correspondent of the *Engineer* attempts to lay the whole blame of English machine-makers not being able to compete with the continental maker entirely to the high wages paid to English mechanics and the short hours they labour. In attempting to confute this statement, I will confine myself to Prussia, Saxony, and Austria. There is not the least doubt but that the individual wages paid to mechanics and other operatives on the Continent are much less and the hours of labour longer than in England; but there is no denying the fact, that where a Continental machine-maker employs two or three mechanics, an English machine-maker only requires one or two to perform the same amount of labour. Is it not a well-known fact that the human machine requires plenty of food and rest to enable it to perform its daily labour? High wages and short hours of labour enable the English mechanic to purchase better food; and, as a natural consequence, when he labours he does so with more courage, and can finish more work in the same time, than the Continental mechanic, who has less wages and longer hours of labour. Probably the correspondent of the *Engineer* can explain the reason why English machine-makers at the present day can send machines of every description for the cotton, flax, and woollen manufactures of Germany, and after carriage-duty, &c., is paid, can undersell the German-made machines from 10 to 30 per cent. Platt, Brothers, and Co., of Oldham, import cotton-spinning machinery into all parts of Germany, and the machines made by them are better and cheaper than those made in Germany, although, you must bear in mind, there is strong competition. Still, for a good, substantial, well-finished, and cheap machine, Platt, Brothers, and Co. stand A 1 on the Continent for cotton-spinning machinery. The same can be said of flax-spinning machinery made by Fairbairn, of Leeds. Derham and Co., of Blackburn, also export steam-engines and boilers to all parts of the Continent, and, after paying mechanics from £3 to £4 per week, with travelling expenses, to fit up their steam-engines and boilers, can make a better and solider job, as the phrase is, than any of their Continental competitors, and give more satisfaction, both as to power and fuel consumed, &c. Such being the case, has not the intelligent mechanic and operative of England something to be proud of? But in order that the English workman may have an idea of the Continental system as regards labour, probably it may not be out of place to state a few facts which have come under my own observation. The cotton, flax, and woollen factories, including bleaching, printing, and dyeing works, work night and day, Sundays not excepted, when the employers require it to be done. Counting-houses, warehouses, theatres, concert and ball rooms, are open, while card-playing, and gambling, and drunkenness, with all its evil consequences, are openly practised on Sunday. Such a state of things, I am sure, our intelligent English operatives would never like to see introduced into England.

"P.S.—At present most of the German states are preparing for a war, and the best mechanics and other operatives are drawn into the ranks of the different armies; and the employers' capital in a great many instances is lying idle and unremunerative for want of skilled mechanics and operatives to increase its value by labour."

HORSE CLEANING BY MACHINERY.

At the establishment of the Manchester Carriage Company, Pendleton, there is now in practical operation a novel and an ingenious system of cleaning horses by means of a steam brushing machine, invented by Mr. Haworth. The idea has evidently been derived from the revolving brush which many hairdressers have had in use, but the application of the idea to horse cleaning is of such utility, and has had so great an effect in economising labour, that it is worth a public notice, especially as we believe the machine is not in use in any other stable. In the lower stable-yard at Pendleton there is a large shed, where ten or a dozen horses can be cleaned at one time. Along the centre of the roof is a revolving shaft, from which hang several endless straps. Each strap gives motion to a horizontal pole, at one end of which is a conical brush that rotates rapidly. On an omnibus horse being brought into the stable, after his three hours' work (during which, in any kind of weather, he removes from the roads of Manchester and Salford an almost incredible quantity of dirt), he is taken to this shed, and a man applies to him the machine brush. In about half an hour the horse is thoroughly cleaned, and only the head requires finishing by hand. The cleaning effected by the machine is much more searching and effectual than the most diligent hand currying can possibly be; and to the majority of animals the greater cleanliness of their skins, as well as the improved circulation of the blood which is produced by the machine brush, appear to be acceptable. Most horses undergo the operation patiently and quietly, but in some animals timidity is produced by the rattle of the machinery. Under the old system, a man was thought to have done a fair day's work if he cleaned ten or a dozen horses, but by the machine he can clean thirty in the same time, and with considerably less bodily labour. When it is remembered that from Pendleton several hundred horses are daily sent out to work, it will be seen how important a saving in money is effected by the employment of this new process.

FIRE ENGINES.

For the re-invention of fire-engines modern society is indebted to the Germans, who gave us the different kinds of water-pump with which the Londoners of the seventeenth century in fortunate cases put a slight restraint on spreading conflagration. In 1518 the citizens of Augsburg possessed certain "instruments for fires," or "water syringes," which were mounted on wheels; but these superior contrivances do not seem to have come into general use at that date or during the next twenty years, as Agricola's "De re Metallicâ," published in 1546, takes no notice of them amongst its remarks on appliances for quenching fires. In 1582, when Maurice had completed the water-works at London Bridge, the mayor and aldermen, with great astonishment, saw him, says Stowe, "throw the water over St. Magnus' steeple, before which time no such thing was ever known in England as this raising of water;" but Maurice's achievements do not seem to have inspired mechanics with a desire to contrive more perfect machines for throwing water upon burning houses. In his old book on "Surveying," Cyprian Lucar, in 1590, describes "a type of squirt, which hath beene devised to cast much water upon a burning house, wishing a like squirt and plenty of water to be alwaies in readinesse where fire may do harme; for this kind of squirt may be made to holde a hoggeshed of water, or if

you will, a greater quantitie thereof, and may be so placed on its frame that with ease and small strength it shall be mounted, imbased or turned to any one side, right against any fixed marke, and made to squirt out the water upon that is to be quenched." Some decided advances were made in the art of building fire-engines in the next generation; for in 1634-5 John Batt, in his "Treatise on Art and Nature," describing "divers squirts and petty engines to be drawn upon wheeles from place to place, for to quench fier among buildings," presents his readers with seven kinds of engines having pumps placed in tubs or cisterns. Shortly before the publication of Batt's treatise, Hautsch's engines were introduced from Germany into London; and three of them were used at the fire on London Bridge. In 1657 Casper Schott, the Jesuit, saw at Nuremberg one of John Hautsch's engines, "which threw a stream of water one inch in diameter to a height of eighty feet when worked by twenty-eight men." Whilst Hautsch's engine was achieving marvels at Nuremberg, John Evelyn's friend, Greatorix, was astonishing London with "his excellent invention to quench fire." But, notwithstanding the advances of mechanical art, the fire-engines of London were found to be absolutely useless during the Great Fire of 1666. The official account of that conflagration states that the "lamentable fire in a short time became too big to be managed by *any engines*."

THE CHINESE COMMISSIONERS IN THE COAL PIT.

DURING their tour in the manufacturing districts, the Chinese Commissioner and his suite visited the coal mine of the Messrs. Bullock, near Birmingham, with the intention of descending, but when they looked down the yawning mouth of the pit, they seemed rather disinclined to venture. They did not, however, like to have their journey for nothing; and, after a short but vigorous conversation in Chinese, they resigned themselves with Oriental fortitude to their fate. Miners' jackets and hats were brought, and they were politely requested to strip off their outer attire, and accept the English costume. Yen-Hwei at this resolutely shook his head, and objected to go down, because, he said, the English people would laugh when they read what a figure he cut, without his fine flowing robe and state hat. After a little persuasion, however, from his Chinese friends, Kuang-Ying and Fung-Yih [the Commissioner and Teh-Ming had remained in one of the carriages], he took off his outer garments, and assumed the dress of the miner. They then stepped on to the square piece of wood which did duty for a tub, and were severally chained fast. They were accompanied by Major Brice and three other gentlemen. Over their heads was what the miners called a "bonnet," to keep off the drops of water. As soon as the platform had been drawn away, Fung-Yih called out "Hold fast," in Chinese; and, as the party plunged into darkness, the Orientals became mysteriously silent. Not a word would they speak, save now and then when the platform gave an ugly tap on the side, when a guttural sound resembling "Ho! hi!" escaped their lips. The passage down seemed interminably long; down, down they dropped in utter darkness every one—Europeans and Chinese—clinging most tenaciously to the chains which looped the platform to the descending wire-rope. The tedium and monotony of the journey was varied by the unpleasant feeling that drops of dirty water were falling down their backs. At length there came the sound of human voices floating up like a distant echo, and in a few seconds the bottom was reached. Then, before any one of the party could be unchained, the "bonnet" tilted, and showered amongst the visitors all the dirty water and bits of coal that had been collected in many journeys. At the bottom, miners, naked to their waists, and begrimed with dirt, awaited the visitors. They politely handed to each stranger a candle, stuck in a bit of clay, and wrapped round with hay. The Chinese gentlemen accepted the candles, but would not stir an inch from where they stood. After some delay a trolly was obtained; on this bags of hay were laid, and the three Orientals, seated thereon, were drawn by a horse along the mine to a large central room, where some hundreds of tons of coal lay about. The miners were evidently much puzzled to know of what sex the foreigners were, and one of them, in a whisper, asked us, "Bean't two of 'em women, sir?" When the party were in the mine, they were joined by the manager, who conducted the party along the workings. The shaft was 400 yards deep, and, considering the character of the visitors, it was a most extraordinary undertaking for them to descend. On reaching the top they declared, one and all, that a coal-pit was a very dirty place, and expressed their determination never to go down another.

SOUNDS.—The gravest or lowest sound which the ear can ordinarily discern is one made by a body vibrating only fourteen or fifteen times in a second; while the most acute audible sound demands for its production no fewer than 48,000 vibrations per second. Dr. Wollaston was certainly correct, that the ear, fine as it is, as well, perhaps, as every other human sense, is adjusted to the discernment only of one finite and allotted span within an infinite universe.

The Useful Metals.

NICKEL AND ITS ALLOYS.

NICKEL is a greyish-white metal, more malleable than iron, eight or nine times denser than water, magnetic, unoxidisable even in moist air, soluble in strong acids, and susceptible of forming alloys with copper, zinc, and iron. This is what chemistry teaches us.

But industry had turned nickel to account long before any of its chemical properties were studied, and by the applications made of it helped to advance science. It was through the studies made upon another metal—cobalt—that we owe the introduction of nickel into the industrial working of the metals.

In 1540, Schurer discovered a substance which had the property of colouring glass blue; this was the oxide of cobalt. It was not until 1733 that Brandt discovered metallic cobalt. Cobalt was, therefore, applied to industry 200 years before it was known what it was, and it has never been applied to any other use since its discovery than it had been before. Only, this use is so important, and nature supplies so little of the mineral cobalt, that it has acquired a value which, up to a certain point, might admit it to rank among the precious metals.

To obtain cobalt blues, which have served from time immemorial to colour glass and porcelain, and incrustations on metals, the cobaltiferous minerals are treated by fusion and oxidation. Almost all the cobalt is oxidised, and it is in the scoriæ, or residues, that the metallic portions called *speiss* are found. The scoriæ were regarded as poor in cobalt, and thrown away as useless, containing nothing but what was at that date called bastard iron, but which is now called *nickel*. Besides nickel, this speiss contained also some foreign metals, such as bismuth, iron, copper, and arsenic; and it is by eliminating some of these metals that we obtain ready-formed alloys, the real composition of which remained so long unknown.

Not until 1751 was nickel discovered by Cronstedt and Bergam, independently of each other, and classed in the rank it now occupies among the metals.

Nickel exists in most cases in meteoric stones. That of Santa Rosa, near Santa-Fé de Bogota, was made into a sword for the Emperor Bolivar. It was two and a-half feet in length. Captain Ross found the Esquimaux in possession of knives composed of the meteoric nickel of Greenland. At Suhl, a metallic composition, known to the Chinese, is employed under the name of white copper, for ornamenting arms and weapons. It resembles silver, and is an alloy of nickel with zinc and copper.

Nickel enters into numerous alloys: among others we may mention argentine, white copper, German silver, packfong, Britannia metal, ruolz, alfendhide, &c. The analysis of tutenag was pursued for a long time only on account of the nickel it contains.

Nickel is a metal which may now be obtained completely pure, and, in consequence of the recent discovery of mines of this metal in Italy, in large quantities. To almost all the properties of iron it adds the whiteness, brilliancy, and unalterableness of silver, even when it is placed in conditions which usually cause the oxidation of the other common metals. These properties render it so like silver, that it is not always easy to recognise which is which, not even by its sonority, which is as well developed in nickel as in silver; and recent experiments have shown that identical effects may be obtained by the graver on both metals.

It is also less fusible than iron, and so little fusible altogether, that if it is sometimes melted in a covered crucible, it is owing to the presence of a small quantity of carbon combined with the metal. It has also the property of cementing like iron, that is, of combining with carbon in such a manner as to produce a metallic body, fusible at a given temperature, exactly similar to steel. This property, which up to the present time has not been studied or utilised, will probably be called to render important services, and help to increase the importance already so justly acquired by nickel.

It is to this property, principally, that we owe all the labours, all the studies upon nickel, and every application hitherto made of it. It forms alloys with almost all other metals, together or separately, without sensibly altering their properties. It has for a long time been employed alloyed with iron, copper, zinc, tin, and silver, in all proportions, and under the best conditions. Almost all these alloys are fusible, and the degrees of fusibility and of unalterability are regulated by the proportion of nickel in the alloy.

Allied to other metals, or completely pure, nickel is always more malleable than iron, and quite as resistant; it is nearly as ductile as silver; it may be rolled, and, just like iron, will acquire the fibrous or granular texture under the same conditions. It can be worked hot, like iron, or cold, like silver.

It is susceptible of producing all the effects of *mat*, or polish, as in silver, without the aid of electrotyping. It also gives the colour and brilliancy of silver to the alloys into which it enters, although in very small quantity. For example, an alloy of nickel, copper, zinc, and iron, which contains only 12 to 15 per 100 of nickel, is perfectly white.

The alloy of nickel with copper and zinc has given the most valuable results; but as it always happens upon the introduction into the usages of life of a new, little-known, and somewhat dear material, industry has, in the employment of nickel, shown itself as cautious as parsimonious. So, in examining the new series of alloys, having nickel for a base, we perceive that, from the first, the proportion of nickel was very restrained; and we can follow its increase with the development of favour for these alloys up to the moment when nickel, emancipated, so to speak, from the triple guardianship of iron, copper, and zinc, finally appears alone, seeking to dethrone silver in the greater number of its applications.

Only eight years ago a metallic article containing nickel would not have been allowed to circulate without being previously galvanised—that is, not without being covered with a coating of silver more or less thick, according to the purpose for which it was intended, and also according to the greater or lesser quantity of nickel it contained. This galvanisation was not, however, useless when the quantity of nickel entering into the alloy did not exceed 10 per cent., as was generally the case. Every one must have experienced how disagreeable the colour of articles styled *nickel* is, which become yellow at the points where the silver wears off.

There is no need of silvering nickel now-a-days: pure nickel resembles silver too much. Its success is complete, and no one would think of disputing the victory. Silver costs about 5s. the ounce; pure nickel about 5s. the pound: the workmanship is the same for both metals. Nickel is employed in the construction of clocks and watches, and in the most delicate jewellery. Optical instrument and philosophical instrument makers generally employ this new metal: for carriages and harness it is extensively employed; and Belgium, Switzerland, and the United States of America, have introduced it as coinage.

Its rarity has hitherto been the cause of the limited number of appliances it has received; but the discovery of a mine of nickel at Cruvino, in Italy, secures a supply for all the wants of industry. Some mines in Piedmont which had been closed upwards of 200 years, were re-opened in 1860. The nickeliferous minerals hitherto recognised are not very abundant by themselves; while, with a few exceptions, the quantity of nickel contained in these minerals is so small, that they can rarely be worked profitably, if they do not contain in abundance some other metal more or less precious. Nickel is found in nature, in the native state, and in meteoric iron, but always allied with iron.

DURATION OF GRANITE.—At a recent meeting of the Society of Arts, an important discussion occurred relative to the value of granite as a building material. The question was asked, at what rate the granite forming London Bridge was being worn away; and to this, Professor Tennant, of King's College, replied that the foot pavement of London Bridge wore away at about the rate of one-eighth of an inch in four years. The effect upon the parapets is best seen at Waterloo Bridge. Some years ago an alarm was raised regarding this bridge, and it was asserted that the granite had decomposed to such an extent as to render the bridge unsafe; but observation shows that this alarm was unfounded. The obelisk of Heliopolis, which is at least 3,000 years old, is still in good condition. We need not, therefore, have much fear for our bridges.

*Landlord and Tenant.**

DISTRESS.

By this name is designated the proceedings that may be adopted by the landlord for the recovery of rent in arrear.

The law gives a landlord privileges beyond any other creditor; for, instead of being compelled to sue at law for an amount that may be due, he may enter the premises and take so much of his tenant's goods as will sell for the sum owing. But it is necessary to the exercise of this power that the rent should not only have become due, but have been refused on application; and, moreover, no one but the actual landlord, or person duly authorised on his behalf, can levy a distress. Thus, if a landlord have parted with his right to the premises, he can no longer enter upon them, whatever sum may previously have become due to him from the tenant.

No distress can be levied on the same day that rent becomes due, nor between sunset and sunrise. Sunday, Good Friday, Christmas Day, or any day appointed for public fast or thanksgiving, are also times when such proceedings cannot be taken. To effect the distress, the landlord is not allowed to enter the house by force, by breaking open an outer door or window, but must effect his entry on the premises in some other way. When once he has so entered, he can seize the furniture, &c., that may be upon the premises, and to resist either him or his agent in so doing is an unlawful act.

If the tenant has clandestinely removed his goods, the landlord is empowered to follow them for a period of thirty days, and during that time he may effect a seizure, whoever may be the owner or occupier of the premises upon which they may be found. If, however, the tenant should remove his chattels at any time before the rent becomes due, the landlord cannot follow the goods, but must sue the tenant after the rent is due, as a creditor in the usual way.

A landlord is allowed to recover, by distress, any sum of money that may be due for rent up to the term of six years. If an execution has been put into the house, and the goods of the tenant are seized by some other party, the landlord is entitled to be paid out of the proceeds of the furniture, &c., one year's rent, if it is in arrear. The same law is in operation if the tenant becomes a bankrupt; but for any sum beyond the one year's rent, the landlord in such cases has only the same remedy as other creditors.

There are certain limitations and restrictions as to the articles that may be seized in distress, the chief of which are in favour of trade. A man's tools and implements in actual use may not be taken, nor may articles belonging to a third party and brought home to be made or manufactured by the tenant. Perishable articles that cannot be restored in precisely the same condition are also exempt from distress, the general principle being that nothing may be taken which cannot be returned in the same state. Deeds and documents are privileged from seizure, as also loose money, but money may be taken if in a bag. Wearing apparel on the person of the owner, a watch in his pocket, and the like, may not be touched.

Goods found upon the premises, whoever may be the owner, may be seized by the landlord; and therefore the furniture of a lodger may be taken, although he may have paid his own rent. In such a case his remedy is supposed to be that he may deduct his loss from the next rent due for the lodgings. Hired furniture, and furniture which the landlord knows to be hired, may also lawfully be seized.

Distress cannot proceed if the amount due be tendered in money, and at any moment before the goods have left the premises the tenant may recover them by paying the rent in arrear. When the goods are removed, notice must be given in writing of the place to which they are taken, and of the intended sale, which is not lawful until the expiration of five days from the distress. An inventory of the goods distrained must accompany the notice. The tenant can then, prior to the sale, still recover them by paying the debt, with the expense of the levy in addition.

The distress should be to a reasonable and sufficient extent, but not beyond; and it must be conducted in a proper and legal manner. Any illegal proceeding renders the distrainer liable to action by the tenant, and to treble costs. The goods must be valued by two appraisers, neither of whom is interested in the distress. The distraining broker cannot himself value the goods. After the landlord's rent and charges are deducted from the amount realised by the sale, the overplus, if any remains, must be paid to the tenant. The tenant is entitled to examine the bill of sale, if he think fit.

The landlord himself is answerable for any illegal conduct of his agent in conducting the distress; but if the distress itself is legal, and some irregularity be committed in its course, the latter is not now sufficient to vitiate the proceedings, though this used to be the law.

In concluding this important branch of our subject, we will add that in any case of grievance or injury, real or supposed, resulting from a distress, recourse should be had at once to the advice of a magistrate or solicitor, who will instruct the complainant how to act.

* Continued from page 356.

Locks and Safes.

The great jewel robberies which have recently occurred in London and elsewhere, have attracted considerable attention to the question of lock and safe security. There can be no doubt but that the opinions evoked on this—everybody's—question (for most people have to trust to a lock), have produced a vast amount of benefit both to the public and the lock and safe maker. There is being done for safes what the great lock controversy of 1851 did for locks. Up to that period the absolute inviolability of "ward," "tumbler," "lever," and "slider" was a canonical dogma of mechanical faith, to doubt which was rank blasphemy. The clever, successful operations, however, of the "light-fingered" Anglo-American suddenly and painfully awoke us from our fool's paradise; and the great firm in Cheapside established a principle of lock-security which has exercised a beneficial influence upon all the leading lock-makers in the realm. We have only to mention the names of Hobbs, Hart, and Co. (the vanguard in the new order of things), Chubb and Sons, Bramah, Cotterill, Price, Tann and Sons, and other celebrated makers—we have only, we say, to mention these "shining lights" of the lock-making world to satisfy ourselves that lock-security has almost reached its climax for the remainder of this century. Each have their special recommendatory qualities, which they can sufficiently explain to the public without any assistance of ours. What we wish to say here is, that the city burglaries have turned inventive heads in the direction of safe improvement. Information has reached us that the two principal London lock-making firms, Hobbs, Hart, and Co., and Chubb and Sons, have been for some time past quietly, and with commendable modesty, making model experimental safes, with the view of ascertaining what amount of burglar-proof security can be attained in such articles.

And this brings us at once to the question of safe security. It must be borne in mind that a safe is expected to fulfil several conditions in combination. It should be sufficiently portable for removal; not too heavy to endanger the flooring of those ancient closets that, in times gone by, when business people were compelled to live where they earned their bread, served for the stowing of the family linen, or the socks and frocks of infant citizens and citizenesses. It should be sufficiently fire-proof to preserve books and parchments from destruction under the usual contingencies of a burning house, and it should also be burglar-proof, for *one night* at least. Beyond such period we don't think that, in the present state of the "science" of safe-breaking, it is possible to make a safe for ordinary commercial purposes, combining the requirements enumerated above, that can impregnably withstand the blowpipe, the drill, and the wedge of a couple of "handy" fellows well up in the nefarious art. Nor do we think it reasonable that safe-makers should be called upon to effect what almost verges on a mechanical impossibility. As well might an iron ship-builder be expected to construct a ship that should be rock and wreck proof, or our friend Captain Blakeley to build one of his "mortal engines, whose huge throats" could never be burst. Let us bear in mind that fourteen or twenty hours is a long time to leave to the attacks of mechanical burglars what is, after all, but a comparatively thin wall of iron. Crime never sleeps; and if the wonderful secrets of scientific research have been brought home, by means of cheap literature and popular education, to the humblest classes of the community, we may rest assured that the descendants of Jonathan Wild and Co. have not stood still and hungry during the general advancement. But, as a supplement to the qualities named above that a safe should possess, it should be easily and readily usable. This latter desideratum is nearly of as much consequence as any other. We must remember that if the "working" of the safe door is troublesome or cumbersome, that clerks in their hurry will not like it, and may occasionally omit to completely fasten everything. We do not now speak of the great banking houses, or other large commercial establishments, where they can afford, as in a man-of-war, to keep at least as many cats as there are mice to catch, but of the legion of moderate-sized active houses of business and offices, where the day is one long race of work to catch the last minute of post-time with the last stamp on the last letter. Yet all these places must have safes; and it has occurred repeatedly, within our own knowledge, that the safe-key has been, absent-mindedly, left in, with sufficient in the cash-box to reward the burglar for the trouble of taking it out. We have seen one very ingenious contrivance that effectually obviates such a contingency. It is called an index lock, and works in this wise: the safe-handle is of the ⊣ form, so as to admit of a good grasp. On the handle face is an arrow, cast as part of the handle itself, in *alto relievo*, with the barb pointing one way and the feather end another. Round the upper half of the handle-plate are the words "locked," "shut," "open," as the case may be; or any other words, to suit special purposes, can be used instead. The handle and bolt action, as a matter of course, form one piece of acting mechanism. Now, it frequently happens that a safe-door will be closed, and no one can tell, without trying, whether it is locked or not. By this lock-indicator, however, the exact condition of the door will present itself to the eye. Should it be merely "closed to," the arrow-head of the handle will point on the word "open" on the right. Give the handle a quarter of a turn, and the bolts will fly into their places, but be capable of being turned back by the same means, without the use of the key. The handle then stands exactly straight up and down, the arrow-head of it resting at the word "shut." Another quarter of a turn, however, passes the bolts still further, when the arrow-head stops at "locked." The door can now only be opened by the key. But the whole operation of locking can be performed at once without any stop, if desired. Thus, it will be seen that, before leaving the counting-house, one glance at the safe-door will, *without the possibility of mistake*, show the position of the bolts; and, furthermore, the key need never be left in the safe-door for any purpose whatever.

But, apart from all this, let us consider that a heavy safe-door, containing constant marketable securities, is being continually opened and shut throughout the day. Unless that door is evenly balanced, there is no managing partner or principal who will care to have his writing, or most sensitive, hand divided in work between the light pen and the ponderosity of the ever-swinging iron slab. Thus, as we approach in thickness of metal towards invulnerability, we have to contend against the concomitant inconvenience of weight in the movement of the door.

Paris and London.—Paris differs from London in some important respects. The manner in which land is owned in France does not give to one class of Frenchmen those large incomes which are enjoyed in England. But Paris being a place of much greater gaiety and fashion, is more the resort of the wealthy and extravagant of other countries. There is less social depravity in Paris than in London. The rich among the French are neither so rich, nor are they so poor, as in London. Paris is, in proportion to its population, a more productive city than London. Some manufactures are carried on pretty extensively in Paris. The workpeople are not so well paid as in similar trades in England, but they do not consume as much food, nor do they perform as much work. Our impression is, that the cost of any given article is nearly as much in Paris as in England, the equality in wages being met by a similar diminution in the quantity of work. The French workmen rarely eat more than twice a day, while English workmen eat four times a day.

Things Talked About.

A WRITER in *Macmillan's Magazine* has been indulging in sketches of cheap popular literature, and he comes to the conclusion that the "common people," who patronise it, are a terribly depraved lot. They love all sorts of imaginative horrors, providing they are seasoned with a due savour of moral reflection. In other words, the "common" people are afraid to be outspoken, but are so little able to discriminate between right and wrong, that if they are told black is white and vice virtue they are perfectly willing to believe it. Says the writer:—"The heart of the *plebs* in this country is not to be reached but in gushes of moral wisdom. Give the poor man sensation; let him sup full of horrors; initiate him in all the mysteries of crime; but always be it remembered that one condition is essential to the success of the dreadful tale—that it shall somewhat ostentatiously ally itself to morality. A good Catholic makes the sign of the cross when he fears that he has got into the company of evil spirits. The honest, beer-swilling Briton of the lower order loves to make moral reflections when he finds himself in doubtful company. He is thus about a hundred years behind the more educated Briton." We happen to know something of cheap literature, and dear literature, too. And we also know that the "beer-swilling Briton" troubles himself very little about any literature whatever. "You are another" is not the best argument in the world; but if we chose to direct attention to the subjects and style of very many of the novels, plays, and operas which find favour with the "more educated Briton," sensational in the worst sense, exhibiting the foulest vices, glossed over with the most mawkish sentimentality, we could show a startling array of "horrors and mysteries of crime," and "gushes of moral wisdom," which would very sufficiently keep cheap sensational literature in countenance. But the writer forgets, or probably never knew, the millions of cheap publications of the most elevating and wholesome character which are yearly circulated exclusively among the working classes. The writer should have made himself better acquainted with very familiar facts before he ventured to sneer at cheap literature.

The House of Commons has passed the Chartered Gas Company's Bill through the second reading by a majority of thirty-one. The House of Lords may yet defeat the measure, and so support the great principle, that all such works should be erected at a distance from populous neighbourhoods, and most certainly very far away from public pleasure-grounds. Encouraged, probably, by the spirit displayed by the defenders of Victoria Park, the inhabitants of the borough of Finsbury are determined that the project of forming a park in the northern district of the metropolis shall be realised in its integrity. The Rev. W. B. Mackenzie, who presided at a meeting at Myddleton Hall a few evenings since, said the Legislature, nine years ago, had allotted to them a very small space of ground; but the Board of Works sought still further to lessen its dimensions by erecting buildings that would interfere with the beauty and utility of the park if ever it was to be obtained. Several resolutions condemnatory of the proceedings of the board were unanimously adopted. The members for the borough have promised their support in the matter, and a deputation has been appointed to express to the Board of Works the popular feeling.

The Sheffield file-grinders appear willing to come to terms with their employers, who, we regret to add, seem unwilling to meet them in a similar conciliatory spirit. Deputations from the grinders, smiths, and hardeners, had interviews with the committee of the Masters' Association last week. The object of the grinders and smiths was to ascertain whether the masters were still willing to submit the list of prices to revision by a joint committee of masters and men. The masters' committee reminded the deputation that the men had rejected the proposition when it was offered to them. The prospects of trade had now greatly changed for the worse, and the committee considered themselves bound, by the resolution passed at the last general meeting of the employers, to decline any proposition for an advance of wages. The hardeners submitted a revised list, and further desired to be employed on piece instead of by the day. These propositions were also declined, the committee being of opinion that manufacturers should have the option of employing their men either by piece or by day, as might appear most desirable.

A number of the most respectable and influential inhabitants of Deptford have come forward to support the dockyard labourers in their request for an advance of wages, and have memorialised the Board of Admiralty on the subject. A claim so supported can scarcely be unreasonable.

The majority of the coal-heavers and quay-porters at Liverpool, who were out on strike, have gone back to work, at the advanced rate offered by the employers; but the seamen and stokers remain out, determined not to resume work until all their claims are satisfied.

A minder at a mill at Ashton-under-Lyne has been committed for seven days to prison by the magistrates at the County Sessions under peculiar circumstances. He was charged with leaving his work without giving seven days' notice, pursuant to contract. The engagement to give and accept seven days' notice was clearly proved, and the general facts of the case were not disputed, but the defendant pleaded that the complainant had broken the contract, inasmuch as the hands were stopped on the morning he left, and he asserted that he had been idle nine days at a time from a similar cause. When he engaged he said he expected to have full work. When they had no work on Friday morning, he walked away with other men, and obtained work elsewhere. In answer to this plea, it was proved that on the morning in question the defendant was only stopped a short time, and then told to go on with his work, but he refused. The chairman said he had only been stopped one hour; but if he had been eight or nine days without work, then he thought the defendant would have been perfectly right in leaving and getting work. A similar case was heard in the borough court of the same town, and the decision was exactly the reverse. It would be very satisfactory if a case were taken to a superior court, so that we might know what is the law of the matter.

Some of the London magistrates have decided on sending cabmen for trial, instead of summarily convicting them, should they, by furious driving, inflict any personal injury. The notice of their intention may perhaps act as a useful warning.

Sir Morton Peto having offered to resign his seat for Bristol, if his constituents were not satisfied with the financial condition of the firm of which he is the head, a meeting of the electors has been held, and forwarded to him a resolution expressive of their perfect confidence in him as their representative.

EMIGRATION ARRANGEMENTS AT NEW YORK.

EVERY man, woman, and child who comes to New York in the character of an emigrant must pass through the office of the Commissioners of Emigration in Castle Garden. Before the passengers of an emigrant ship leave her, their luggage is taken charge of by officers of the institution, for which numbered metal tokens are given. Both the passengers and luggage are then landed by the aid of a steam-tug belonging to the commissioners. After this, the passengers pass through the landing-office, in front of a series of desks, where their names, age, profession, country, the name of the vessel they arrived in, their destination, and the names of such friends or relations to whom they are going (if they have any) are booked. They are then forwarded to boarding-houses, which are licensed by the municipal authorities, and under the direct patronage of the commissioners. The custom of these houses is made to depend upon the manner in which their keepers conduct their business; they are not only required to treat the emigrants fairly in their charges, but they are held accountable for such property as may be entrusted to them by the lodgers. The luggage left in the Garden can be called for when it suits the convenience of the owners, and whether removed soon or late there is no charge made. If an emigrant intends to remain in New York, and his luggage is such as he cannot carry away, it will be forwarded to his address at a much lower rate than he could have done it by engaging a conveyance himself. Those emigrants who are going to the interior of the country are forwarded by the commissioners, in their own steamers, either to the railway stations or the vessels by which they are to travel; and in order to prevent their being imposed upon, they are supplied with tickets which will free them to their destination, in whatever part of the States that may be. When the emigrants leave New York for a distant part of the country, the commissioners do not lose sight of them, but, by means of their agents in many of the distant towns, provide asylums for the indigent and employment for the able-bodied. The class of emigrants who are without the means of transporting themselves to the interior of the country, have loans granted upon such luggage as they may possess, which they can redeem when in employment, and no interest is charged for the money. The commissioners are also agents for employers over the whole of the States, so that they are enabled to find situations for emigrants in almost any of the branches of industry. Their employment office at the landing building is a highly valuable institution. By means of this office numbers of young girls are saved from moral shipwreck.—*The Working Man in America.*

WHAT WE OWE TO INVENTORS.—Inventors have set in motion some of the greatest industries of the world. To them society owes many of its chief necessaries, comforts, and luxuries; and by their genius and labour daily life has been rendered in all respects more easy as well as enjoyable. Our food, our clothing, the furniture of our homes, the glass which admits the light to our dwellings, at the same time that it excludes the cold; the gas which illuminates our streets; our means of locomotion by land and by sea; the tools by which our various articles of necessity and luxury are fabricated, have been the result of the labour and ingenuity of many men and many minds. But mankind are all the happier for such inventions, and are every day reaping the benefit of them in an increase of individual well-being as well as of public enjoyment.—*Self-Help: New Edition.*

Notes and Extracts.

THE passage of a rifle bullet through the brain would not occupy more than the thousandth of a second; a stroke of lightning would pass through the body in much less time; thus a person killed by either of these means would die without consciousness having time to be produced, as proved by the aspect of those who have thus died.

DR. ANGUS SMITH, when travelling in a railway carriage, collected some of the particles of dust which floated in the air, and which seemed to shine with a metallic lustre. On examination these were found to be in reality rolled plates of iron, which seemed to have been heavily pressed and torn up from the surface.

THE LAW OF LIMITED LIABILITY.—Several of last week's papers contain remarks upon Vice-Chancellor Wood's judgment in the case of the "Anglesea Colliery Company," 14 W. R., 708, showing the most total misapprehension of the nature of that decision. It is not the case, as there represented, that the Vice-Chancellor has held that the holders of fully paid-up shares are liable to further calls, but the holders of shares not fully paid, are liable to calls made for the sole purpose of adjusting the equities between them and the fully paid-up shareholders, and that these latter are "contributories" for that purpose, *i.e.*, for the purpose of receiving the proceeds of, not of paying, the call.

MINERAL OIL AS A SUBSTITUTE FOR COAL.—A series of important experiments upon Mr. Richardson's method of burning mineral oil as a fuel for steam-ships and steam-engines, was terminated recently at Woolwich Dockyard with complete success. Ten pounds of water is the highest quantity that has ever been evaporated per pound of the best steam-coals: upwards of eighteen pounds of water has now been evaporated continuously for many hours by oil from the celebrated Torbane Hill or Boghead mineral. The trials with other rock oils, though not reaching quite so high a figure, have been such as to prove the superiority of mineral oil over coal, and the perfect capability of maintaining the strongest fire without the slightest cessation or diminution of its intensity, until the complete exhaustion of the store of fuel.

DIVING AT THE THAMES EMBANKMENT.—Opposite Buccleuch House there is a diver descending a ladder, supported on scaffolding, into the water. He is bent upon giving assistance in the task of removing piles no longer required. There are five men in attendance upon him. First, they weight him with metal weights, slung from his shoulders over his diver's dress. His helmet is on, and the round glass in front of the face screwed tightly up. They fasten a rope to him. He steps into the water, which rises to his knees, his middle, his shoulders, and finally closes over his head as he descends from rail to rail. The other two men in attendance on him pump air through a flexible tube, which descends with him into his helmet. A shovel is first lowered to him, then an auger. The water flows on as before. Craft of all sorts pass and repass; still there is no sign of him. The looker-on begins to feel an oppressive shortness of breath and sense of anxiety. His thoughts are unconnected, thinking now of the naked pearl-divers in warm Indian seas, wondering almost simultaneously whether this mysterious stay of the well-clad being below the water was another of the secrets that the river would never tell, recurring to the pearl fisheries, and the shark-charmers that accompany every pearl-fishing expedition. At last, half an hour has elapsed. There is a slight commotion among the attendants, and the diver's helmet appears above the water.—*Builder.*

A WORD FOR LANCASHIRE.—A noble county, be assured, is that of Lancaster, notwithstanding its tall chimneys, and black-mouthed coal-pits, and smoke-begrimed faces, and swarthy artisans, and cotton-covered operatives. The Southern shrinks from it as a pestilence. The Londoner would almost as soon be stuck up to the neck in a Tipperary bog as be fixed in a manufacturing town. But, over the wide world, point out to us a district of the same extent as Lancashire with the same properties of greatness. In this much-maligned county there are fields as green, and landscapes as fair, as eye can rest on. Nowhere is agriculture, in its science and practice, advancing more rapidly. From beneath its surface coal is dug out by brawny arms to turn the machinery of the monster factory, and to cheer the fireside of the humble cottage. From its mountain-sides the stone is quarried in abundance. Along its picturesque valleys the dancing waterfall is made available for turning the wheels of the mill, and the wild beauties of Nature are trained to the service of the practical and useful. Railways intersect the county like net-work, affording unusual facilities of transit. On its rivers float the argosies of a hundred lands; and from its ports are borne its manufactures to the four corners of the earth. Its inhabitants are characterised by a sterling intellect of Saxon parentage, polished and whetted by the daily attrition of commercial dealings. Many a strong mind has struggled up from the weaver's loom, till it has enriched the literature of the day, or increased the comforts of the day by its practical inventions. A county, indeed, not without its failings; but still a county "whose merchants are princes," whose women are said to be "witches," and whose people generally, though rough and gnarled in their outside bark, are, in the main, sound at the core!

Co-operative Intelligence.

Poole Co-operative Society.—The committee of this society, which has been in existence since February last, have just issued their first report. It is as follows:—"Your committee have great pleasure to report that the sale of goods for the quarter has amounted to £263 16s., realising a net profit of £19 19s. 5d., after providing for the necessary expenses incurred in establishing the society. The society consists of eighty members, with a share capital of £112 14s., and a deposit capital of £15. The average takings per week amount to £20 5s. 10d. The society, therefore, have a surplus equal to a bonus (after allowing a dividend of 5 per cent. on shares) of 2s. 6¾d. in the pound on the amount of purchases made by paid-up members prior to 30th April, which purchases amount to £157 0s. 11½d. The committee invite members to deposit sums of not less than £5, repayable in not less than six months, to carry interest at 5 per cent. They therefore hope that the members will see it is to their advantage to deposit their savings with the society, so as to enable the committee to go to first-class markets for goods."

Ossett Co-operative Society.—From the nineteenth quarterly report it appears that the society is in a flourishing condition. After paying all expenses, and 5 per cent. on capital in £1 shares, the committee purpose paying a dividend of 2s. in the pound on £2,433 purchase money, leaving a balance of £10 8s. 9¾d. to carry to the reserve fund, making a total reserve fund of £31 6s. 3d.

General Information.

CLUBS AND INSTITUTES.

Notice to Working Men's Clubs and Institutes.—The council of the Working Men's Club and Institute Union beg to give notice that they have abolished the annual fee of 5s., payable by clubs affiliated to the Union. The registration fee of 2s. 6d.—payable by clubs on their first coming into Union—will still be payable.

The Spottiswoode Choral Society's annual concert was held on Monday evening, the 11th inst., at the Great Hall, Whittington Club, and deserves noting as a most gratifying *réunion* of employers and employed. The programme comprised a choice selection of sacred and secular music of the highest order, rendered with considerable skill both by vocalists and instrumentalists. It is certainly an indication of an improved relationship between capital and labour when, after working hours, the employer participates in, and even leads, the rational recreation of those he employs.

EMIGRATION.

The Time to Emigrate to Canada.—It is important that the emigrant should arrive early in spring. By leaving home in April or May, he will get to Canada at a time when labour is in general demand. The highest wages are paid during harvest; but his main object should be to procure employment by the year, thereby securing a home for the winter. It must be borne in mind that until he becomes acquainted with the ways of the country, his services are not of much use to the farmer, and he should, therefore, be particularly careful not to fall into the common error of refusing reasonable wages when offered to him on his first arrival. On no account should the agricultural labourer be persuaded to emigrate to Canada after the month of August, unless he is coming out to friends.

Female Emigration to Australia.—Miss Maria Rye, who has just returned to England from a visit to the Australian colonies, whither she proceeded three years ago with 100 women emigrants, was present at a recent meeting held at the offices of the Social Science Association, in London. Colonel Sykes presided, and Miss Rye read an interesting account of her visit to the antipodes. She was received with great cordiality, and her statement was listened to with much attention, and greatly applauded. She described the colonies as being excellent, not only for their climate, but for the abundance of their products, and the absolute certainty there was of obtaining all the necessaries, and most of the comforts, of life by all who chose to work. She first visited New Zealand, describing Otago as an excellent place for settlement. She left the 100 young women she took out to that district there, and she had since received information that all of them, except some three or four who came to her with false characters, had done well. She afterwards visited Canterbury and Nelson. After leaving Nelson she visited Marlborough, Picton, and Wellington. She described the land in the neighbourhood of Auckland as igneous in its origin for at least fifteen miles round, and mentioned the fact that, from a hill in the middle of the town, at least twenty-five extinct volcanoes could be counted, and stated that the land was in many parts covered with large masses of scoriæ. The town itself was of a purely commercial character. She then went on to describe her visit to Australia, and gave a very glowing description of the vegetation, the flowers, and fruits of Sydney and its neighbourhood. Here she was much pleased with the arrangements for the reception of female emigrants. She afterwards went to Queensland, and described the vegetable productions of Brisbane and its neighbourhood as something wonderful. Rows of pine-apple trees growing like cabbages, while the tea and coffee trees, the sugar-cane, arrowroot tree, cinnamon, and bamboo, were all growing one alongside of the other. Honey could be obtained from the bush trees by buckets full, and the coast was covered with oysters. There were very good arrangements for the reception of emigrants at Brisbane, but she informed the company that nothing could be more discreditable than the manner in which they arrived at the port, crowded together in the vessels, squalid and dirty, while in some instances the death-rate on the voyage had been from 30 to 70, or, in other words, from 9 to 20 per cent. She next went to Victoria. The town of Melbourne was, she said, one of the finest she had seen, both as regarded the public and private buildings. Arrangements were entered into by the Government to grant 150 free passages for female emigrants per month, but the Colonial Government refused any grant for the immigration of educated women, on the ground that the Colonial Legislature only contemplated granting funds for the assistance of the labouring emigrants. She was, however, of opinion that there was a great demand, both in New Zealand and Australia, for governesses; and she considered that if any mistake had been made by the society, it was in sending out young women who were not sufficiently accomplished. Indeed, persons possessed of the highest accomplishments were always in request, and invariably did the best, though all did well.

INDUSTRIAL EXHIBITIONS.

Provincial Exhibitions in France.—The Bourdeaux exhibition is one of the most important after Paris, and the amount expended for works of art this year exceeded £2,057; of this, nearly £1,200 was paid by private persons for 60 works, rather over £800 for 34 works purchased by the society by which the exhibitions are instituted, and £60 by the authorities of the town for one picture; the total number of works purchased being, consequently, 95, and the average price between £21 and £22 each. In the list of the painters whose works were sold are the well-known names of Rousseau, Antigua, Landelle, Boulangé, and two of the medallists of the present Paris Exhibition—Claude and Brown.

Correspondence.

*** *We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* Working Man, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*

We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

THE "WORKING MAN" LIFEBOAT.

To the Editor of the Working Man.

Sir,—I am very glad to find that the subscriptions for the purchase of the Working Man Lifeboat are beginning so well. In my opinion the matter is one which concerns us working men more deeply than appears at first sight. The sailors who man our ships are as truly and really working men as are ourselves. Their fathers and brothers are generally working men, and they have to undergo in an aggravated form all the hardships and discomforts which sometimes appear inseparable from working class life, for with them it is often all work and no play, especially during the tempestuous weather of the winter months. We are always ready to club together for the purpose of assisting such of our mates who may, by reason of accident or illness, have been thrown out of work, and I do not see why we should not also assist in saving, in times of danger, our fellow-workers on board ship. But for them we should not have many of the materials from abroad, the manufacture of which gives so many of us employment; nor should we be enabled to send to foreign markets the goods so made. Consequently, I hope that every workshop and factory—from the large establishment, with its thousands of hands, to the little shop, with its half-dozen workers—throughout the United Kingdom, will assist in promoting an object which has for its aim the development of those fraternal feelings which have ever characterised us working men as a class. There are few working men who, if they beheld a vessel in danger, would hesitate to assist in rescuing the despairing crew and passengers; and when we can do so without danger to ourselves, without even the need to leave our work-bench or home fireside, I say that we ought to do all we can in the matter. I quite agree with what has previously been stated on the subject in the Working Man, and hope that, when the proper time comes, I shall have the pride and satisfaction of gazing at the messenger of hope and mercy, purchased with the hard-earned pence of us working men, as it stands in the midst of the great industrial display which will be held this autumn in the Agricultural Hall.

A Working Man.

EMIGRATION TO AMERICA.

To the Editor of the Working Man.

Sir,—I was much pleased with the article on "British Columbia" in No. 22 of the Working Man. I once thought of emigrating to the United States, and read the works of various writers respecting that country. But I was not satisfied after all I had read, having an objection to the climate. Since then I have received a letter from a brother of mine, dated Chicago. He states that "the chief portion of the people of this part of America are Germans, or the descendants of Germans. It requires a hardy race of men to live here. Many who come here are not prepared to stand the heat of summer or the cold of winter, and sell their farms, half improved, for very little." Hence it will be seen that some thought is required before deciding upon emigrating to the United States.

J. H.

TO CORRESPONDENTS.

Antiquarian.—Pews are of comparatively modern origin. In the primitive churches the worshippers stood upright or sat upon the ground. Towards the year 1319, stools were placed in the churches, but a decree was needed in order to put a stop to fights to obtain these seats. About 1530, reserved benches were established, with the initials of the proprietors placed upon them. About 1614, we find mention of pews carpeted and cushioned like those of the present day. The high enclosures were introduced by the Puritans in order to escape the notice of the royal officers, who took note of those who did not bow when the name of Jesus was mentioned. Swift says massive bedsteads of ancient form, like those which our fathers used, have been transformed into pews; but they have not changed their nature, for they always offer a refuge to those who wish to sleep.

Artisan.—It was in 1825 that a bill was introduced into Parliament, enacting penalties for overwork in factories, and limiting the hours of labour on Saturdays from twelve hours a day to nine hours.

J. N. W.—"Any master convicted of having employed any person contrary to the provisions of the Factory Acts, or having employed any child without a certificate from a schoolmaster, is liable to penalties varying from one to five pounds for each child, young person, or woman so employed." 7 Vict., c. 15, s. 56. "Parents or guardians who receive a pecuniary benefit from a child's wages are liable to penalties varying from 5s. to 20s. for neglecting to cause the child to attend school." 7 Vict., c. 15, s. 57.

N. L.—Yes; it is possible to see the wind. The *Scientific American* says: "Take a polished metallic surface of two feet or more, with a straight edge—a large hand-saw will answer the purpose. Take a windy day, whether hot or cold, clear or cloudy, only let it not rain or the air be murky—in other words, let the air be dry and clear; it is better if the wind be steady, but this is not essential. Hold your metallic surface at right angles to the direction of the wind—*e. g.*, if the wind is north, hold your surface directed east and west, but instead of holding the surface vertical, incline it about 45° to the horizon, so that the wind, striking, glances and flows over the edge (keeping it straight), as water over a dam. Now sight carefully over the straight edge at some minute and sharply defined object, and you will see the air flow over as water flows over a dam. Make your observation carefully, and you will hardly ever fail to see the air, no matter how cold; the result is even better when the sun is obscured."

Apprentice.—The only authorised persons in London for the engagement of seamen, apprentices, and boys are—The Superintendents of the Government Mercantile Marine Offices, Minories; Sailors' Homes, Dock Street and Poplar; and the licensed Government Agents, Messrs. Suckling and Co., 11, America Square, Minories; and Messrs. Besant and Co., 84, Lower Thames Street. Any other person (except the shipowner, master, or mate, or the *bonâ fide* servant of the owner) providing berths for any seaman or apprentice is liable to a penalty of £20 for each offence.

Emigrant.—All persons, not having before resided in Queensland, paying their own full passages to the colony, receive a £30 land order (equal to thirty acres of land) for each member of their families of twelve years and upwards, and a £15 land order for each child between twelve months and twelve years. Free and assisted passages are given, without restriction as to age, to persons of the following occupations:—Shepherds, ploughmen, roadmakers, quarrymen, professed gardeners, miners, carpenters, masons, bricklayers, blacksmiths, wheelwrights, shipwrights, &c.; also female domestic servants of good character. Apply at the Queensland Government Emigration Offices, 2, Old Broad Street, London.

Builder.—The use of proper printed forms for an apprentice's indentures is allowed by the law.

A Wood Carver.—To answer all your questions would fill a page of the Working Man. You could not obtain a passage on the terms mentioned by you, nor is it certain that your condition would be improved by emigrating. If you are a steady, skilled, and industrious workman, your chances are as great at home as abroad.

J. R. B.—The short-hand system mentioned by you is the best.

A Working Man (Blyth).—While sympathising with you and your fellow-workmen in your struggle, we must decline the controversy which would inevitably follow the insertion of your letter.

S. J. Cooper.—Your excellent communication has been anticipated by us.

F. P.—Your suggestion has been complied with.

Metropolitan and Provincial

WORKING CLASSES' EXHIBITION and INDUSTRIAL FESTIVAL, to be held at the AGRICULTURAL HALL, London, and opened on SEPTEMBER 3rd, 1866.

TO EXHIBITORS.

Contributions of Skilled Workmanship, or Amateur Productions, will be accepted from all parts of London, the Provinces, Scotland, Ireland, and the Colonies. For the benefit of Provincial Exhibitors, the Railway Companies have liberally offered to return unsold goods free, so that the expense of carriage will be but half the usual charge.

NOTICE.—Applications for Space must be forwarded on or before the 30th of June.

SPECIAL PRIZES.

The Council of the above Exhibition have much pleasure in announcing that, in addition to the MEDAL OF MERIT, designed for the occasion by J. S. and A. B. WYON, Esqs., the following SPECIAL PRIZES have been liberally offered by the gentlemen named, for the production of Articles to be Exhibited at the Agricultural Hall in September next, namely—

£15 0 0 in Money, or Silver Cup, for the MOST USEFUL INVENTION. Open to all Classes. The Gift of the Directors of the Agricultural Hall Company.

£10 0 0 in Money, or Silver Cup, for the best PAINTING IN OIL. The Gift of the Directors of the Agricultural Hall Company.

£5 0 0 in Money, or Silver Cup, for the second best OIL PAINTING. The Gift of C. COMFORT, Esq.

£5 0 0 in Money, for the best WATER-COLOUR DRAWING. The Gift of J. HARRIS, Esq.

£3 3 0 for the best GOLD BROOCH and EAR-RINGS, of Original Design, which can be sold for £10. (Sale for that sum to be permitted if required.) The Gift of JOHN HOLMES, Esq.

£2 2 0 for the best pattern, Birmingham make, GILT BRACELET, BROOCH, and EAR-RINGS, which can be sold for £3 3s. (Sale for that sum to be permitted if required.) The Gift of JOHN HOLMES, Esq.

£2 2 0 for the best Specimen of WHITBY JET JEWELLERY.

£2 2 0 in Money, for the best WORKING MODEL of a STEAM-ENGINE. The Gift of W. J. W.

£2 10 0 for the best ARTICLE OF UTILITY, made by an Amateur. The Gift of R. MURRAY, Esq.

£2 2 0 and a Silver Medal, the Gift of R. MURRAY, Esq., for the best WORKING MODEL of a MILL to grind Stale Crusts into Flour.

£2 2 0 for the best PEN-AND-INK DRAWING. The Gift of W. STRAKER, Esq.

Sec.* [5

The Original Chlorodyne,

Invented by R. FREEMAN, Pharmaceutist, is allowed to be one of the greatest discoveries of the present century. It immediately relieves and cures Coughs, Colds, Consumption, Influenza, Bronchitis, Asthma, Whooping Cough, Cramp, Spasms, Gout, Diarrhœa, Dysentery, &c.

EARL RUSSELL communicated to the Royal College of Physicians and to Mr. Freeman that he had received information from Manilla that the only remedy of any use in Cholera was Chlorodyne.—*Lancet*, Dec. 31st, 1864. See *Times*, Nov. 14th, 1865.

Freeman's Original Chloro-

DYNE.—The *Medical Times*, Jan. 13th, 1866, states—"It has an immense sale amongst the public, and is prescribed by scores of orthodox medical practitioners, and, of course, it would not be thus singularly popular did it not supply a want and fill a place."

Freeman's Original Chloro-

DYNE engraved on the Government stamp outside every bottle. Sold by the Inventor and Manufacturer, R. FREEMAN, 79, Kennington Park Road, London, S., and most Chemists. In bottles, ¼ oz., 1s. 1½d.; 1¼ oz., 2s. 9d.; 10 oz., 11s.; 20 oz., 20s.

Caution! Beware of spurious, deceptive, and dangerous imitations. Ask for Freeman's Original Chlorodyne, and see that you have none other. [6

Gathered from the Waters.

For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1857, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the Shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,000 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C. [8

Notice.—The renewal receipts for the Christmas quarter are now in course of payment.

52, Cannon Street, and Queen Street, London, June 6th, 1866.

The Annual Meeting of the EMPEROR LIFE AND FIRE ASSURANCE SOCIETIES was held at the Guildhall Tavern, on June 6th, Ebenezer Clarke, Esq., in the chair. The report showed that during the year 1,577 Proposals had been received, amounting to £357,701, and 1,402 Policies had been issued for £317,572. The Claims in the Life Department for the year had been only £3,831, or about equal to the Premiums of the last four months. The Fire claims amounted to £632. A Bonus had been given to the Life-Participating Policy holders from 22 to 48 per cent. on the Premiums previously paid, and a Dividend was declared to the Shareholders at the rate of 5 per cent., free of income tax, and a Bonus of 1 per cent. The total amount of Life and Fire Assurances effected was £2,649,782. Advances had been profitably made on Freehold and Leasehold Securities during the year, and new Plans introduced to meet the requirements of second-class Lives, Members of Building Societies, and others. In consequence of the increase of business, the Directors had found it necessary to enlarge their present offices, and to purchase the lease of their own and the adjoining premises. The retiring Directors, N. J. Powell, Esq., Richard Harris, Esq., Rev. F. Trestrail, and F. Straker, Esq., were unanimously re-elected.

FRANCIS RAVENSCROFT, *Manager*. [14

The Planet Permanent Building and Investment Society, Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and all further information may be had of EDMUND W. RICHARDSON, Secretary.

B. Prew's Wardrobe.

At this splendid new building you'll see a display
Of all the new fashions, the first of the day;
If well dress'd you'd be, and at lowest price, too,
"Then come to my wardrobe," says Benjamin Prew.

If frock or Oxonian you should require,
And really are choice in this part of attire,
Wishing best of material, with style that is new,
"Then come to my wardrobe," says Benjamin Prew.

If a coat you should want, for business or dress,
Or a waistcoat of which you'd approval express,
Or trousers to fit, cut on system quite new,
"Then come to my wardrobe," says Benjamin Prew.

If you have any boys, and would see them well dressed,
In clothes to wear well, and become them the best;
Or want Knickerbocker suits for young children, too,
"Then come to my wardrobe," says Benjamin Prew.

Every one buys of Prew, so well known is his name.
If you study your int'r'st you'll just do the same;
If you'd dress in the fashion, and save money, too,
"Then come to my wardrobe," says Benjamin Prew.

Children's Knickerbocker Suits from	12s. 6d.
Boys' Eton, Harrow, and Rugby Suits	21s. 0d.
Boys' Cricketing Suits	21s. 0d.

The Judgment on Jamaica.

THE copious blue-books on the Jamaica insurrection presented to Parliament, have been followed by a despatch from the Right Hon. Edward Cardwell to Lieut.-General Sir H. K. Storks, Captain-General and Governor-in-Chief of the island of Jamaica, which embraces the official sentence of the Government upon Governor Eyre.

Nothing quotable can better indicate the stupendous nature of the inquiry which has been instituted, than the fact that Mr. Cardwell begins by quoting question 46,634. Mr. Cardwell lays down a very clear doctrine as to the province of the military during martial law. The excuse for the wholesale floggings, burning of houses, and hangings, was the advantage which the terror of the very name of martial law was calculated to inspire, and that examples of severity helped to render good government possible. Mr. Cardwell states that "future good government is not the aim of martial law. Example and punishment are not its objects; its severities can only be justified when, and so far as, they are absolutely necessary for the immediate re-establishment of the public safety." Here we get a wholesome and intelligible doctrine, which limits the use of the murderous knife of the military. It is not their business to create "examples," that is the business of juries and civil judges. It is not the business of the military to cater for "good government;" with these political functions they have nothing whatever to do. Their sole business is to ensure the "public safety." They may knock down or shoot people in arms, and arrest those likely to use them; but they have no right to kill but in pure self-defence. The official statement of this doctrine is condemnation of the general acts of the Jamaica authorities. Mr. Cardwell states that "Her Majesty's Government are compelled to express their concurrence—1. That the punishments inflicted were excessive. 2.

HARDENING THE PENS. (*See page* 402.)

That the punishment of death was unnecessarily frequent. 3. That the floggings were reckless, and at Bath positively barbarous. 4. That the burning of 1,000 houses was wanton and cruel."

That, indeed, is a remarkable line—"That the punishment of death was unnecessarily frequent." Surely, murder was never described in gentler terms; for every unnecessary execution is murder. Governor Eyre's defence was, that though he authorised martial law, he was not aware of what was taking place during its continuance. Mr. Cardwell observes that, "if it were deemed necessary to continue martial law, it was the duty of the Governor to inform himself of the character of the proceedings taken, and to put an end to all proceedings which were not absolutely necessary, and therefore justifiable on the ground of necessity. Her Majesty's Government cannot, therefore, hold the Governor of the colony irresponsible either for the continuance or for the excessive severity of those measures."

With respect to the trial and execution of Mr. Gordon, Mr. Cardwell says—what is undoubtedly serious, and fixes for ever the character of the acts—that "they are events which Her Majesty's Government cannot but deplore and condemn;" and he orders his despatch, and the judgment it contains, to be published in the colony of Jamaica. It states that the British Government "would not discharge their duty by advising the Crown to replace Mr. Eyre in his former position as Governor." What ulterior proceedings it will now be the duty of Parliament to take in the matter, we will not anticipate by conjecture. We content ourselves with expressing satisfaction that Mr. Cardwell, whose amiable and gentle disposition must have rendered the task he has performed very repugnant to him, has, nevertheless, discharged his duty with honesty and firmness, and has written his despatch in terms which will assure the people of Jamaica that their hope of justice from the Crown of England has been well-founded, and will restore the character of British colonial government to its rightful place in the eyes of the world.

Pens and Pen-making.

Who was the inventor of the steel pen? We fear that his name, like that of the individual who ate the first oyster, is destined to remain unknown to the millions who, otherwise, would be eager to render their acknowledgments to their great benefactor. What should we do without steel pens? Why, it might as well be asked, What should we do without the printing-press? Like the railroad and the electric telegraph, steel pens have become one of the necessities of the age. In the days when four-wheeled coaches were deemed the *ne plus ultra* of locomotion, and when a journey from the metropolis to the midlands was a task involving several days' preparation, folks were content to use quills, which they cut and mended at their leisure. But after a time men grew weary of continually mending pens, and so, after many attempts and failures, the steel pen came into use—not the article with which we are now familiar, but one mounted in a bone case, and known as "Wise's Pen." This was at the beginning of the present century; but there is reason for believing that the invention was of earlier origin, steel pens having been imported, about 1780, from Tunis and Tripoli into Holland.

It was not, however, until a comparatively recent period that steel pens came into general use, and to Mr. Joseph Gillott, the celebrated manufacturer of Birmingham, belongs, in a great measure, the honour of having rendered the steel pen cheap, good, and popular. His establishment, in Graham Street, Birmingham, may fairly claim to be ranked among the "Workshops of the World," for its productions are famous over the whole face of the globe, while to the commercial man, whether at home or abroad, a "Gillott" is almost as indispensable as his "Bradshaw." A wonderful place is this pen manufactory. It is an immense brick building, described by a bewildered "special correspondent" as being an edifice "which looks something like a large asylum, a little like a manufactory, and more like an hospital than either," with which graphic description the reader must be content, for our business is not with the outside, but the inside of the place.

Very interesting is it to follow the steel from the moment of its being cut into long strips until it issues forth in the shape of a "magnum bonum," or the well-known "swan quill." The steel, which is made from the best Swedish iron, is cut into long thin strips of the requisite width by a machine made for that purpose, and which in appearance resembles a hand chaff-cutter. The steel strips are then subjected to a series of processes, by means of which they lose their hardness and brittleness, and are freed from the oxide with which they were covered. They are then "rolled" until they become of the proper thickness. During this operation they are occasionally dipped in oil, the rollers being kept cool by means of a small stream of cold water constantly falling on them.

The long, thin strips of white, glittering steel are next taken to one of the long workshops which form the upper part of the factory, and which are remarkable for their light, warm, and well ventilated character. These rooms lead one into another, and are filled with crowds of clean and busy workers, principally women and girls, the number employed being between 500 and 600—thus solving one of the most important questions connected with the healthy and remunerative employment of women. Entering one of these rooms, we find it filled with a number of presses, at each of which a female is seated busily employed in the cutting out of "blanks," an operation which will be easily understood by a reference to the annexed diagram, which shows a portion

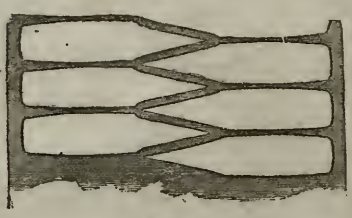

Fig. 1.

of the steel ribbon after the blanks have been cut out of it. The steel is placed under the press, and by a rapid yet methodical movement the blank is accurately cut. We subjoin illustrations of three different forms of blanks, the largest being intended for a barrel pen, such as the

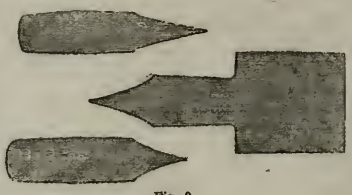

Fig. 2.

magnum bonum. The swiftness of the punching operation is almost marvellous, especially when we consider the seeming perplexity of the process. The steel has first to be carefully adjusted on the die, then the punch has to be brought down, and as each blank is cut out, care has to be taken to avoid waste. The number of blanks generally cut in one day by a female is 300 gross, and as each gross contains 144, the gross total thus cut would be 43,200. The operation strongly resembles the old schoolboy trick of moving the hand rapidly backwards and forwards under a regularly descending penknife. For one description of pen a steam press is used, but for all the others, presses worked by hand labour alone are employed.

The pens are next carried from the blank-cutters to the *side-slitters*; after which they are pierced, the two operations sometimes taking place together. A kind of annealing process is then gone through, for the purpose of preparing the blank for being stamped. The stamping-press is exquisitely contrived, and the girl who works it, places the flat blank side slit on the die, her foot works a treadle, and the next moment out comes the pen impressed with the required inscription. After this, the blank is *snappered*, or rendered of a half cylindrical shape, and, in the case of the magnum bonums, to have the broader part of the blank made completely round. Up to this point, the pens are in a soft state, and, for practical purposes, useless. They have the form of the finished article, but nothing more. To render them of the requisite hardness and elasticity, they are taken to a room in the basement of the building, where the furnaces are kept glowing in a manner which makes the atmosphere unbearable to those not used to it. Here the pens are placed in iron boxes, each capable of holding several gross. The boxes are lifted by means of a pair of tongs into the furnace, where they remain for about half an hour, after which they are taken out, and the contents dexterously emptied into a tank of oil. After remaining for some time in the oil, they are strained by the inner tin in which they are placed, and which is pierced with holes, being withdrawn from the outer one. They are then placed in a kind of revolving sieve, and the oil which clings to them drained off by centrifugal force. So far, good. Now, our pens have to be cleansed. This is accomplished by putting them in a number of barrels, which are made, by means of steam power, to revolve on a common axis. These barrels are filled with sawdust, which is found to be well suited for the process. The cleaning process is followed by that of scouring. A second series of barrels are filled with pounded casting-pot and water, together with a little quicklime to prevent rusting, and the pens being placed in this mixture, are whirled rapidly round for the purpose of removing the scale left by the action of the fire. This done, they are removed to the grinding-room, where the ear is saluted with a noise resembling the hissing of a forest of snakes. Each pen is held in a pair of peculiarly-constructed pincers for a few seconds against a wheel of birch-wood, cut across the grain, and carefully loaded to prevent jarring. Each wheel is covered with leather coated with glue and emery, presenting a perfectly smooth surface. The pens are ground, firstly, longitudinally; secondly, crosswise, so as to ensure the requisite amount of elasticity being obtained. The workers, principally females, display great expertness in this delicate and seemingly difficult process.

The pens have now to be coloured, much of their popularity depending on the beauty of appearance possessed by them. They are put into a kind of coffee-roaster, consisting of a simple cylindrical barrel, raised above a clear fire, and worked by means of a long handle. Here they are subjected to a regulated degree of heat, until they acquire the blue or brown tinge required, when they are removed, and allowed to cool upon an iron plate. Five minutes suffices to give the pens a bronze colour, and ten minutes the well-known rich purple colour. The degree of hardness possessed by them is denoted by the lightness of the tint, and its diminution by the blueness which supervenes. After being coloured, the pens are placed in a solution of shellac in spirits of wine, and exposed to the open air, so that the spirit may evaporate, and leave the shellac in the form of a delicate white incrustation on the pens. This incrustation, on being subjected to a proper degree of heat, melts, flows over the pens, and presents, when cool, a beautiful enamelled surface.

The pens are subsequently separated, and conveyed to a room where the final process—that of slitting—is performed, after which they are taken to the warehouse, where they are sorted, arranged, and placed in the fancy boxes in which they are usually sold. A box of common pens, which in 1830 cost 8s., can now be obtained for 6d.; at the same time the quality is much superior. Mr. Gillott employs a large number of hands, who find plenty to do in converting the tons of steel into countless numbers of pens. Well may it be said that the day of little things is not to be despised. Pens, like pins, are insignificant-looking objects, but they play an important part in our economy, laying the basis of great fortunes, and affording employment to thousands of men, women, and children.

*Landlord and Tenant.**

LODGINGS.

It is a large proportion—perhaps, a considerable majority—of our working men who do not occupy premises entirely themselves, but either let or hold apartments. For the benefit of such of our readers as may be of this number, we will therefore briefly explain the law as to Lodgings.

It is always well, in taking or letting apartments, to have a written agreement, that there may afterwards be no dispute as to the terms on which they are let; but where there has been no such agreement, it is the rule that the period at which the rent is paid, whether weekly or otherwise, is the term of the tenancy, and corresponding notice to quit must be given. But if the lodgings be merely taken for a short and definite term, with the understanding that the lodger will quit when that term has expired, no notice is necessary. The forms of agreement and notice between landlord and tenant which we have given in a recent number are applicable, with verbal alteration, to the letting of apartments.

We have already mentioned, when treating of the subject of Distress, that the goods of a lodger may be distrained by the landlord for rent due from the tenant; they may also be distrained for the tenant's taxes; and it is, therefore, advisable in all cases to ascertain, if possible, the position of the person from whom the apartments are taken, and whether he is free from arrears.

The tenant or occupier of a house may distrain the goods of his lodger for rent overdue, in the same manner that the landlord can exercise that power; and the same rules of law apply in both cases. The door of the lodger's apartment, however, may not be broken open to levy a distress, for that is considered his outer door. If there be any inner apartments, and admission be gained to the first by proper means, those inner apartments may be forcibly entered.

The householder can prevent the goods of the lodger being taken off the premises while any rent is due; but if the lodger be allowed to remove, his landlord cannot follow the goods, but must proceed for the rent in the county court, as for an ordinary debt.

In the case of furnished apartments, the sum which the lodger may agree to pay for their use is not considered by the law as entirely rent, and therefore the householder is not allowed to distrain for the whole amount on property his lodger may possess. It is held that a portion of the sum is for occupation of the apartments, and a portion for the use of the furniture; and it is only for the former that the householder may distrain. It is therefore well, in letting furnished apartments, to divide the amount that may be payable, assigning so much for use of furniture, and placing moneys received to that account until it is clear.

If the occupant of furnished apartments absent himself, and there is reason to believe that he has left without intention to return, a police constable may be summoned, the apartment broken open in his presence, and any goods or property of the lodger that are left behind may be secured. Then, after fourteen days' notice has been given by advertisement in the *London Gazette*, the property so taken may be sold, for payment of the rent in arrear, unless the lodger previously appear to discharge the claim. The surplus of such a sale, after deducting the rent, must be reserved for the lodger on demand.

If a person occupying apartments should refuse to give up possession, the householder should serve him with proper notice to quit, with an additional clause inserted, to the effect that on the expiration of the term such a sum will be charged as additional rent, if possession be still retained. If this is not sufficient to induce the lodger to leave the apartments, a summons may be obtained at the registrar's office of the district County Court, and after a hearing of the case, the judge may make an order to the high bailiff of the Court to obtain possession for the landlord.

We will conclude these papers on the law of landlord and tenant by a reference to the subject of

FIXTURES.

All fixtures that may be taken by agreement on entering premises of any kind, should be included in a written list, with the value of each article attached. This is well not only for the prevention of dispute, but also in case of transfer afterwards to an in-coming tenant.

Any fixture attached or let into the freehold in such a manner as to form a part thereof, cannot be removed. It has been held that summer-houses, green-houses, &c., attached to posts fixed in the soil, are irremovable, though the same, if resting on and not let into a brick foundation, may be taken away.

Buildings and erections put up for the purposes of a trade or calling, are removable, if built upon brick or stone foundations, and not in any way let into the soil, or attached by mortar, &c., to the original building.

With regard to the interior of the premises, any chimney-pieces, shelves, &c., put up for ornament or domestic convenience, may be removed, but the property and the previous fixtures must be left in the state in which they were before such conveniences were attached, or the tenant will be liable to the landlord for dilapidations. Shelves, &c., are only removable if affixed by screws; if nails are employed, they become the property of the landlord.

Lastly, all fixtures which the tenant may claim must be removed before the expiration of the tenancy, and cannot afterwards be taken without the express consent of the landlord.

* Concluded from page 396.

WILD ANIMALS.

From the last annual report of the Zoological Society of London, it appears that the number of animals living in the Regent's Park menagerie at the end of 1865 was 1,956, being 98 more than at the corresponding period of the preceding year. Among the acquisitions made during the year were some of especial interest. Perhaps the most important among them is a pair of African elephants, obtained in the summer of 1865, which have supplied what has long been rather an important desideratum in the society's series of mammals. Although the Asiatic variety of this huge creature has always had one or more representatives in the menagerie, the measures adopted by the council to procure a specimen of the conspicuously different African species had not previously proved successful. Up to the summer of last year, it is believed that no example of the African elephant had ever been introduced alive into this country, at any rate since the time of the Romans, whose elephants are generally considered to have been of African origin. In July last, however, the council succeeded in obtaining by exchange a young male of this animal from the Jardin des Plantes of Paris, to which institution two specimens, both of this sex, had been some time previously presented by some dusky potentate in the interior of Africa, desirous of propitiating his formidable neighbours. Soon after the receipt of the male African elephant, two females, singularly enough, came into the London market, one of which was likewise secured by the council for the sum of £500. The society's collection therefore now contains a pair of African, as well as a pair of Indian elephants. It likewise includes a pair of hippopotamuses, a pair of Indian rhinoceroses, four giraffes, and six or seven elands, forming such a collection of the larger and more bulky mammals as has never before been brought together in one place; not to mention the various series of lions and tigers, and other better-known animals, which are maintained in their accustomed numbers. Another conspicuous addition that has lately been made to the Regent's Park collection is the sea bear, or, as it is more correctly called, the eared seal, belonging to the genus *Otaria* of naturalists, a single specimen of which was acquired some months ago, and has deservedly attracted much attention. The form of this animal, although well known to distant navigators, is one altogether novel to those who have not visited the Antarctic regions or the Pacific coasts of America, and its actions, as exhibited by its keeper, are as *bizarre* and grotesque as anything which it is possible to conceive. The mode of progression of the *Otaria* is utterly unlike that of the seals of the Atlantic, which are only enabled to move on *terra firma* by the contraction and expansion of the abdominal muscles, and it more nearly resembles that of the walrus. The present specimen was captured by the same man who has now the charge of it, and to whom it seems to be devotedly attached, on the shores of Terra del Fuego, near Cape Horn.

The Paris Exhibition of 1866.—A new order of reward has been established in connection with this institution; this reward is to be bestowed on institutions or associations, whose object is exclusively the establishment of a better understanding between the workmen and their employers. One single prize of 100,000 francs for the individual, the establishment, or the locality which has best succeeded in realising this intention, is offered, besides ten other prizes of 10,000 francs each, to be distributed amongst those who have in a minor degree co-operated in this great work.

*The Foresters.**

HOW THE FORESTERS HELP A BROTHER.

Perhaps it may be asked what the Order of Foresters has accomplished greater than "benefit societies" or insurance offices? We will endeavour to answer the question. These societies simply agree to pay a certain sum in sickness and at death; and as long as the society is enabled to perform its contract in this respect, the end is accomplished. So, probably, thought the Foresters at one time; but as time rolled on—as the Order increased—it became evident that man's wants are not confined to these narrow limits. The great fact became apparent that man is "a creature of circumstances"—one day borne on the wings of prosperity, and the next smitten down by the rude blast of adversity; one day mingling with the companions of years—crossing the scenes of "boyhood's home," enjoying all the pleasures and friendships of his native place—and the next, at the caprice of his employer, by the vicissitudes of trade, or other emergencies that perpetually dog the path of not only the working man, but the tradesman, he is compelled to seek among strangers, in some distant locality, wherewithal to maintain himself and family. Old associations perhaps induce him to linger till the last moment in the neighbourhood where he had formerly gained an honourable livelihood; but the pressure of circumstances soon compels him to seek further ere he can again settle down to employment or business.

Now, this is the gist of the whole question—Of what avail, at that hour, to him is the insurance office or the isolated benefit society? Why, instead of being a benefit, it is absolutely a drag to him—that is, if he intends to keep up his subscription; but he sees little practical utility in doing so, because he may never return to his former locality; and the probability is, that his subscription for years may be forfeited and lost to him.

Now, it is precisely in this dilemma that the Foresters lend a helping hand to a brother. Whereas other societies of the kind alluded to would leave the member in the middle of the stream, literally, "to fish for himself," the Order safely lands him on the other side with a few little fishes and a loaf in his pocket. Previous to starting on his weary and almost unknown journey, the forlorn member is provided by his Court with "travelling checks," each of the value of 1s. 3d. One of these he can cash daily in any locality where a Court is held, and there is scarcely a town or village of the United Kingdom that does not contain one or more. He goes to the Court, and gets his check cashed, and also receives contributions from the Court to which he applies; there being a *Relief Fund* for that very purpose in most Courts of the Order. Here, instead of being among strangers, he finds the welcome hand of friendship at once held out to him. He finds himself among many in his own trade or business, who readily give him every requisite information as to obtaining employment. He knows at once whether to stay, or still to push further on; and if the latter is the alternative, an additional sum is generally collected, to help him on his way. Should he fall ill, still he is sheltered, though far from home, and all his wants attended to. The brothers in the locality where this misfortune may overtake him visit him, pay his sick claim, supply medical attendance, and, in fact, treat him in every respect as though he were a member of their own Court; and, in the event of death, his remains are decently interred in their final resting-place.

As observed by Mr. Watkins, from whose admirable pamphlet we have borrowed many hints—Where is the insurance society or benefit club that can present advantages like these? Were he a member of either of these, he would be among strangers in the hour of trouble, and, perhaps, the only shelter for him would be the poor-house or union. Are not these sufficient inducements—founded on positive facts—for every man to give preference to an Order displaying such forethought in meeting every ill that flesh is heir to? And is it surprising, now that these facts are so widely spread, that every village and hamlet should aim at establishing Courts in all directions? That even in Australia, America, India, and other distant colonies and

* Concluded from page 375.

possessions where the English flag waves in its might, the Ancient Order of Foresters gathers recruits, ever augmenting—Forestry everywhere following closely in the wake of commerce and emigration—opening Courts and forming Districts, and receiving a brother from Old England in the same manner, and with the same friendship, that he finds at home—in all this, we say, there is nothing to surprise us; on the contrary, it is only the natural consequence, the natural effect of an adequate cause, by the very nature of things, and in accordance with the economy of Providence.

But Forestry did not, and does not, stop there. As Courts increased, Districts had to be formed; and when men of practical experience were thus brought together, it was still found that other contingencies had to be met—that a still greater field for the extension of philanthropy was before them. Members became aware of the fact that their widows and orphans required protection, and that this could only be accomplished by the strenuous efforts of the members whilst living. What thinking man could quietly sit down and imagine his labour done, when the fact was before him that he should only leave his widow and orphans £12 or £13 to support them in the event of his death? Men had seen numerous happy homes broken up, and the widows and orphans of a respectable brother tossed about on the rude waves of adversity, and at last taking refuge in the poor-house.

Such a possibility had to be provided against. Already, in the London United District of Foresters alone, there are hundreds of widows and orphans receiving assistance—very material aid, if not entire support; and the expenditure of this District in this item has risen from £1,200 per annum in 1859 to over £5,000 at the present time.

It is true that the sum of 2s. 6d. per week for each widow, and 6d. for each child under fourteen years of age, is a small sum; but it at least keeps a shelter over their heads, and the amount will, doubtless, be augmented with the increasing prosperity of the District.

In connection with this subject, we may state that, from the large surplus fund in hand, this District contemplated the creation of an Almshouse, or Retreat for its indigent members and their widows and orphans; but, considering the great reduction of the funds that would result from the cost of the building and its management, the scheme was abandoned, and, we believe, very properly, on that score alone, but still more in consideration of the fact that all such places are objectionable on account of their constraint, and the absolute necessity for enforcing those stringent regulations, without which they must become most objectionable. With a small but certain income, the poor easily find comfort amongst their relatives and friends, and can fructify their labour for their own benefit, and the advance of the social state in general. It will certainly be always infinitely better to save the cost of brick and mortar in order to support human flesh and blood.

Such, then, is Forestry. Its laws are just and liberal, and fashioned after the purest models of government; for the greatest amount of individual liberty consistent with the general welfare of the whole body is secured to every member. Assumption of power and arrogance of demeanour may be immediately checked by the deposition of the presumptuous; the rights of every individual member are scrupulously respected and guarded; each individual has equal rights and privileges; merit alone is the only medium through which posts of honour may be arrived at; and no artificial barriers are permitted to prevent virtue and talent from occupying their fitting station. There is no secrecy about Forestry; it courts inquiry by the publication of numerous reports and its "Directory," which is the annual history of the Order. Moreover, it encourages literature amongst its members by the publication of the *Foresters' Miscellany; or, Quarterly Review*, which is the organ of the Order.

Besides being united to render less trying the vicissitudes of human existence, the Foresters likewise assemble to promote the social happiness of the brethren, and relieve their minds occasionally from the pressure of care amidst this fretful state of human struggle, with temperate conviviality. But as home, with all its fond, endearing ties, should have a prior claim to our regard, the exhilarating influence of kind hearts, cheerful songs, and merry company should never be permitted to seduce us from a strict attention to the interests and happiness of our families. Consequently all brawls, absurd and disgusting speech, and drunkenness are utterly interdicted in their assemblies. They inculcate that a good Forester is a man who, though jealous of his rights as a citizen, maintains them in a temperate, manly, and decorous manner; whilst, at the same time, he knows his duties, performs them well, and pays a ready and willing obedience to his country's laws—neither cringing nor servile on the one hand, nor wild and factious on the other. In his private character, as a father, son, or husband, he fulfils the relative claims of these states with scrupulous fidelity. Honest, sober, and industrious ought every member to be; and if there should be one amongst the members who is not so, he is not a good Forester.

Forestry emphatically inculcates thrift and forethought, and triumphantly demonstrates *what can be done with money*. Money, as we are solemnly told, is the root of all evil; and yet without it very little good is found to grow here below. True, it complicates the relations of social life; it baffles the exertions of simple industry; and it is the immediate cause of three-fourths of human crime; and yet, when well applied, it is the mightiest lever of human welfare. Countless generations to come will attest this fact in the case of Mr. Peabody and his more than royal benefaction.

But the *million sterling* or more of property owned by the Foresters, contributed, heaped together by the working men, is of the same nature as a mighty engine of good, and countless generations, in like manner, will have reason to bless Forestry as one of the great and good ideas that Providence sometimes permits and enables man to apply practically for the amelioration of our condition here below.

ANTHRACITE COAL.

Hitherto the difficulty of smelting iron in South Wales with anthracite has proved nearly insuperable, owing mainly to two causes—decrepitation and the consequent production of refractory agglomerations of anthracite dust and slag, whereby the working of the furnace has been either greatly deranged or actually stopped. The late Mr. Crane was the first person who attempted, many years ago, to use anthracite in the smelting of iron, at Yniscedwin Works; and it is at the same works that this important problem seems to have been at length satisfactorily solved by Mr. S. H. Blackwell. Many failures had to be encountered, and the project was about to be abandoned as hopeless, when, fortunately, it was decided that a final experiment should be made. The internal form of the furnace was modified four months ago, and ever since the results are stated to have been entirely satisfactory. The ton of pig iron, of the qualities known as Nos. 2 and 3, is now produced in the furnace with a consumption of less than one ton of coal. The report for the week ending June 10 shows that in that week 128 tons 4 cwt. of pig iron were made with 112 tons 10 cwt. of coal, in the proportion of 1 to 0·88. This is a great achievement, and one which may be justly regarded as of national importance. In the United States there is a fine quality of anthracite, which has been largely applied to the smelting of iron, but with a consumption of nearly two tons of coal to one ton of pig iron. Weight for weight anthracite contains more heat-giving power than any other kind of coal; but as it does not directly yield volatile inflammable gas, like ordinary bituminous coal, it has not been used in reverberatory furnaces, where flame is required. It is, however, demonstrable that by suitable arrangement copious and intensely hot flame may be generated exclusively from anthracite.

Notwithstanding the numerous explosions at the Hazardville Powder Mills, U.S., plenty of men can be had for two dollars per day to fill the places of the killed or injured. So does familiarity breed contempt of danger.

A Collier's Position.—Mr. Warrington W. Smyth, of the Government School of Mines, writes as follows to the proprietor of a steam coal mine in the Aberdare Valley, Cardiff:—"It is a matter of surprise to me that you should meet with any difficulty in obtaining plenty of men, when I see what high wages can be made in your pits. Why, it pays a young man better to cut coal with you than to be an officer in the army or navy, or to be a curate in a church; and, as you give your workings plenty of wind, what with your furnaces and your great ventilating-machine, there is nothing to complain of with respect to unhealthiness of occupation. There are thousands of good fellows in our tin and copper mines who work hard, and often in very poor air, who would be glad enough if they could make half of the amount which an industrious man is able to ensure himself in some of your steam coal collieries."

*Locks and Safes.**

Mr. Chatwood, of Bolton-le-Moors, has recently patented a safe, upon the united merits of which he challenges both popular and scientific criticism. The Chatwood safe lately underwent a series of tests before the mayor and corporation of Bolton, which, as far as they were carried, were pronounced perfectly satisfactory, and so certified accordingly. The application of the wedge was omitted, as it was, at the time, considered useless. This omission was noticed in an article in the *Mechanic's Magazine*, with the remark that such a test must be a very expensive one; in fact, it involves nothing less than the destruction of the door of the safe. To this Mr. Chatwood replied, in a letter to the same journal, dated April 5, stating that the question was not one of expense, as each purchaser is allowed "to submit his safe to thirty-six hours' test before delivery, and we pay £100 if he succeeds in opening it." Being six months in arrears with orders, Mr. Chatwood is not able to give up a safe to the wedge and sledge-hammer, but promises one on the first opportunity, regardless of any expense whatever. The Chatwood safe has from 2½ in. to 3 in. of solid steel, made in a peculiar way; and he hurls unqualified defiance at blow-pipe, drill, chemicals, wedge, and gunpowder. We have already heard that more than one "destructive" mechanical artist is making arrangements to get at the £100. However that may be, there can be no question of the Chatwood safe strongly competing for a front rank place in the modern "safe" brigade.

Powder-proof locks form an important element of safe security. Mr. Chatwood says that they should not contain space for more than 1 dwt. of gunpowder. We suppose he means in a vertical position as the safe stands on the floor. Taking this position, there are several locks that will not hold half that quantity. Mr. Hart, of Hobbs, Hart, and Co., has contrived a lock that will only take 16 gr. of gunpowder under any amount of charging; but the horizontal powder-plugging will vary, in the various powder-proof locks, from 60 gr. to 16 gr., the larger spaces having outlets for the explosive force in the lock-chamber.

Let us turn for one moment to the fire-proof arrangements, the great desideratum in which is the preservation of parchment deeds. It is well known that the writing on parchment can all be steamed off "as clean as a new whistle;" therefore, what will preserve the scribble on the sheepskin will preserve anything else. As to the best mode of doing this, there seems to be some difference of opinion among safe-makers themselves, though all are agreed with respect to its great importance. Some years ago, Mr. George Price, of Wolverhampton, submitted this part of the question to experiment by the able hands of Mr. Herapath, of Bristol. Mr. Price, in addition to being a patentee and manufacturer of locks and safes, has cultivated the trade in all its aspects with such a devotion that he has absolutely created a literature for it. Let us hope that he has met with a commensurate reward. There is a kind of freemasonry among true brethren of the pen that always begets a kindly feeling, and an earnest wish for success, whether amateur or professional. Well, the result of Mr. Herapath's labours were, that parchment bore a *dry* heat effectively up to 300°, when kept from contact with metal, but that it would not stand anything like that test if the heat was in a moist condition. Some of the modern safes have special arrangements to counteract the effects of steam heat, and thereby preserve parchment. It is somewhat singular that, until very recently indeed, the scientific engineer has never been invited to the workshop of the safe-maker. Had he been, the specifications of bygone years, the crumbled tiles, slate, and broken crockery, would never have been put forward as some of the primary elements in safe construction. But the public is greatly to blame in this matter. "Cheapness! cheapness! cheapness!" is the universal cry, forgetting that quality is a most essential ingredient in the comparison of price. We are often amused, when taking our strolls, to notice, when passing among the second-hand office-furniture dealers, the *things* in iron that they call "safes." Such articles might answer very well to keep the tea and sugar from Betty, if that obliging young person was in the

* Concluded from page 396.

habit of giving cup-and-saucer parties on her monthly holiday afternoons, but—and here we repeat it—*but*, as far as any other kind of security is concerned, the deluded purchaser will discover on the very first actual trial how truly a fool and his money were soon parted.

Again. The concoctors of our jumble of Patent Laws have a great deal to answer for. The word "patent" is the greatest *ignis-fatuus* of manufacturing industry that could possibly be devised; it covers a multitude of "horrid" sins, and is used on every occasion where sharp practice is the order of the day. We hold that selling any article to the public with the word "patent" upon it, unless such patent really exists, should be treated as a misdemeanour and punished accordingly. Furthermore, that all patentees should be compelled to show to the public what it is to which the patent applies; by which means the said public would be in a position to know what they were buying, and the honest inventor would not be shamelessly victimised by what are neither more nor less than barefaced trade forgeries. Take one of these very articles—locks. In nothing is the word "patent" more grossly perverted. Without descending too much into particulars that might look like, in earnest, calling a spade a spade in these days of lingual refinement and expressional delicacy, we will ask, How many lock-makers and lock-dealers are able to justify the use of the word "patent" on many of the locks they sell to their customers with this decoy stamp upon them? When a patent has expired, the word should be erased from that peculiar construction of the article, and its continuance declared a trade forgery or fraud upon the public.

It may be said that in the discussion of the weakness of our lock and safe securities, we are instructing the thief. In answer to that we cannot do better than conclude this paper in the words of the celebrated French savan, Réaumur, on this very subject:—

"But is there not this danger, that at the same time we shall be giving lessons to thieves? It is not very probable that they will seek instruction of us, or that they have any need of it; they are greater masters in the art of opening doors than we can pretend to be. Let us, then, learn the art of opening locked doors, in order that we may acquire that of securing them in such a way as to leave little or nothing to be feared on account of their security."

In a forthcoming number we shall say something on the universal question of locks, both general and special, and relate a few singular instances of the penny wise and pound foolish economy that generally reigns amongst us, and of the up-hill and heart-sickening work of trying to prevail upon people to lock the stable door BEFORE the steed is stolen, instead of *afterwards*.

USEFUL HINTS.

THE best alloy for making taps for beer-barrels is—for the body of the tap: tin, 785 parts; antimony, 195; nickel, 20. For the key the best proportions: tin, 807; antimony, 175; nickel, 20; or, tin, 715; antimony, 215; and nickel, 70. These alloys are quite inoxidable under ordinary circumstances, and are the result of careful study.

DEODORISERS.—The following articles are easily available for the suppression of noxious gases, so fatal to health and life:—Two pounds of sulphate of iron (copperas) dissolved in a pailful of water, and poured into a vault, will prevent the formation of sulphuretted hydrogen gas for some time, and will generally be sufficient to remove all nuisance. A layer of charcoal dust will prevent the escape of all offensive odour from any decomposing substance. One pound of nitrate of lead dissolved in a pailful of water, is excellent for sinks, sink drains, and vaults. If other things fail, chloride of lime is always effectual, and may be freely used in vaults, and upon other collections of filth. These substances are not expensive, and will effectually destroy all the offensive smells. The quantity to be used will depend on the quantity of filth to be deodorised, and their permanency of effect upon local conditions in each case.

THE INTRODUCTION OF STEAM FIRE ENGINES.

IN 1856 Messrs. G. Rennie and Son constructed a portable disc engine and disc pump for the Woolwich Dockyard. This engine was mounted on wheels, and could be used either as a steam fire engine or as a pump for emptying the caissons. It had a cylinder 13 in. in diameter, and a 9-in. pump, and weighed about 2 tons, being 6 ft. long, and the same in height. At its official trial a height of discharge of 120 ft. to 130 ft. was obtained, the discharge being at the rate of 30 tons per hour, and the pumps making from 300 to 400 revolutions per minute. Messrs. Shand and Mason produced their first land steam fire engine in 1858, and two years later Mr. James Shekeltou, engineer, of Dundalk, constructed the first steam fire engine ever made in Ireland, and which works well, being still in use for fire duty. The London Fire Engine Establishment used a land steamer for the first time at a fire in Doctor's Commons. This engine appears to have been in some respects inferior to Mr. Braithwaite's first engine, and worked so indifferently that after a ten months' trial it was withdrawn. It was, however, soon replaced by one on a different construction, which closely resembled that of Mr. Braithwaite. In 1860 Mr. William Roberts—with whose labours in the cause of steam fire engines and volunteer fire brigades our readers are, doubtless, familiar—fitted a steam tug with a pair of his double-action twin-pumps. Each pump had two 11½-in. cylinders, with 12-in. stroke, the discharge being 30 gallons from the two at each stroke. They worked most satisfactorily, having paid for themselves at a single fire. During the same year Messrs. Merryweather appeared for the first time in connection with steam fire engines. They constructed, from the designs of Mr. E. Field, C.E., a steam floating fire engine for the Tyne Docks. This engine had two inclined steam cylinders, 16-in. diameter and 12-in. stroke, and two pumps each of 9-in. diameter and 10-in. stroke. Messrs. Merryweather's first land steamer was constructed in the following year, Mr. Field again furnishing the design; this was the well-known *Deluge*, which proved a perfect success. The *Deluge* was of 30-horse power, with a single horizontal 9-in. cylinder and 15-in. stroke, and a double-acting horizontal pump 6½-in. diameter and 15-in. stroke, worked direct off the piston-rod of the steam-cylinder, doing away with crank-shaft, crank, fly-wheel, connecting-rod, &c., which had previously been used in this class of engine. The reign of steam fire engines appears now to have commenced, for their manufacture proceeded briskly, Merryweather and Shand alternately coming before the public with a new production. Shand manufactured three engines for the London and North-Western Railway Company to run on rails, and an engine for the town of Gothenburg, besides some engines for the London Fire Establishment. Merryweather, although not so widely patronised as Shand, brought out the well-known *Torrent*, which has done such good service in many a London fire. This was in 1862, in which year Messrs. Lee and Larned, of New York, sent one of their small-sized rotary pump engines of 5-horse power, which won good opinions for its workmanship and finish, as well as for its satisfactory working.

PUTTING THE PENS IN BOXES. (*See page* 402.)

Railway Accommodation for the Working Classes.

THE improved means of transit afforded by the railway system, which has for more than thirty years exercised so marked an influence throughout the British Isles, has affected no class of society more powerfully than that large section of the community whose lives are devoted to labour. In the old coaching times, the luxury of travelling, on account of its unavoidable expenses, could only be enjoyed by the wealthy. Railway travelling, now so general, has so far changed this state of things, that the working classes participate to a considerable extent in the advantages it affords to the entire community. The first public benefit caused by the introduction of railways was the system, enforced by Act of Parliament, of running once a day, in each direction, a train at 1d. per mile. At first such trains started at unreasonable hours, and their rate of progress was attended with so much loss of time that a long journey almost consumed the limited period at the disposal of the working man. It is about twenty years since some of the time-tables announced that "third-class passengers were conveyed by the *slow train* at 1d. per mile." At present, so completely is the rate of travelling accelerated, that third-class passengers travel as rapidly, and in some few instances more expeditiously, than those who are conveyed in first or second class carriages.

Certain portions of the manufacturing districts may be reached by the Great Western Railway, and to promote through communication over other lines without change of carriage, the narrow gauge has for several years been laid down within the regular broad gauge rails. By the facilities thus afforded, third-class passengers may book from Paddington by the 8.0 a.m. train for Birmingham, Wolverhampton, Chester, and Holyhead, changing at Oxford into the 10.0 a.m. express from London. There are many other large towns embraced by the Great Western system to which the same facilities are offered by this line of railway to third-class passengers. The London and North-Western line runs to many towns in common with the Great Western, and affords even larger opportunities of travelling at third-class fare by certain trains. Many of these places are not given in the large official bills of the company, but are detailed at length in the smaller books, where much space is occupied with the enumeration of towns in the manufacturing districts where communication is afforded to the third-class traveller between one town and another, in addition to the cheap fares from London.

In the more immediate neighbourhood of the metropolis the advantages of reduced fares are clearly exhibited. The London and Brighton line has enjoyed the honour of inaugurating the cheap excursion system to Brighton, and other watering-places on the south coast of England. One great boon to the poorer classes not generally known ought to be here stated. This company issue third-class return tickets to every station on their line, excepting express trains. There are several third-class trains daily between London and Brighton, not including the Sunday and Monday excursions, which latter run at less than the ordinary single fares. On the suburban branches of this railway the fares are remarkably low, and every train has first, second, and third class

carriages attached. As an illustration, the cheap ride of 36 miles for 9d. between Victoria and London Bridge, and *vice versa*, by any train, may here be noticed. A more agreeable ride for a working man at a low charge cannot be met with elsewhere, the passenger travelling through the Crystal Palace grounds and the pleasant suburbs of the south of London.—The London, Chatham, and Dover Railway—a line only constructed within the last five years—possess an enormous traffic on their Metropolitan extension line, but the suburban range embraced is not quite so extensive as that of the Brighton Company. The third-class trains on the Chatham and Dover main line are very numerous, and return tickets are issued to all stations by ordinary trains. This company have recently increased their workmen's trains to three in each direction, at 1s. weekly fares, with the option of returning by any train after 5.30 p.m.—A large number of trains, many of them having third-class carriages attached, pass over the suburban branches of the South-Western Railway during the day.—The Mid-Kent line from Charing Cross and London Bridge, and likewise the Greenwich, sustains an equally large amount of traffic, at very low fares, both on week-days and Sundays.—The North London and Blackwall Companies run trains every quarter of an hour in either direction for fifteen hours daily, but there is no third-class. Reform has long been wanting in this matter, and the second-class fares might either be slightly lowered between the shorter distances on these two lines, or cheaper third-class fares introduced.—This leads us to notice the Metropolitan Railway, which, though only open three years and a half, has met with the most extraordinary success, and yet without in any way reducing the ordinary omnibus traffic near which it passes. At the present time about 180 trains in each direction travel daily from Moorgate Street, Aldersgate Street, and Bishop's Road, Paddington, from 6.5 a.m. till 12.15 midnight. These trains are all first, second, and third class, and the benefit to the public afforded by this line must be evident from the fact that a passenger will always be in time for a train, and never has to wait more than five minutes at the utmost. Two trains in every hour run on to Kensington, and three to Hammersmith; to both these places the third-class single fare is 4d.; and the return is 6d. from Farringdon Street, or 1d. and 2d. additional from Moorgate Street. The fare to Bishop's Road is 4d., return 6d. The fare from one station to the next, in any direction (except between Farringdon Street and King's Cross), is 1d. We need not be surprised after this to find that in the year 1863 as many as 8,455,175 passengers travelled over that portion of the line then open; the following year, 11,721,889; and in the first half-year of 1865, when a further reduction was made in the third-class fares, 7,462,823. In one single week 370,843 passengers were conveyed, and in one day 83,440. There is every reason to believe these numbers are at the present time considerably increased; for, twelve months since, as many as 1,200 workmen travelled by the cheap trains for their use, at 1s. per week. Three of these workmen's trains run daily in each direction, giving the holder of the ticket the option of returning by any train.

From the above enumeration it is evident that the working classes are the principal supporters of a railway company, when the fares are sufficiently moderate to admit of their travelling to reasonable distances. The Board of Trade returns reveal the astonishing fact that as many as 200,000,000 persons of all classes annually travel over the 12,000 miles of railway now open throughout the kingdom. This computation does not include the holders of season tickets. In every train there is a larger proportion of third-class carriages than first and second, and there can be no doubt that the great bulk of railway travellers is composed of those who pay third-class fare. When the various lines now in course of construction are completed, the means of rapid transit in the neighbourhood of London will be largely increased, with a corresponding benefit to those to whom railway travelling is most beneficial—the working classes.

The Metropolitan Railway is 4¾ miles long, and its traffic during the Whitsun week amounted to £4,856, which is above £1,000 for each mile in the week. The number of passengers conveyed over the line was 484,900.

A YEAR OF THE RINDERPEST.

It is a melancholy fact that the rinderpest, although happily greatly abated, has now existed in the United Kingdom for an entire year, the first cases having been officially noted in Great Britain in the week ending June 24, 1865. We have not yet a complete year's figures as to the progress of the malady; but the weekly attacks are annexed for fifty weeks, back cases being included:—

Although the ravages of the disease have been greatly mitigated, it will be observed that even now the number of attacks is as large as it was in September, when the subject excited a far larger increase of public attention than it does at present. The Contagious Diseases Prevention Act, 1866, which came into operation towards the close of February, will be seen to have been attended with the happiest results. Up to the enforcement of a policy of slaughter and isolation the disease continually extended its ravages, the attacks noted in July, 1865, having been 2,290; in August, 4,821; in September, 6,122; in October, 7,955; in November, 16,240; in December, 38,532; in January, 1866, 49,287; and in February, 57,004. In March, when the new Act had got into working, the attacks sunk to 35,986; in April they further declined to 15,836; and in May to 14,734. In the current month they promise to exhibit a still further decrease.

HOW TO MAKE MAGIC PHOTOGRAPHS.

Take, in the first place, an ordinary print—a card-picture, for instance—on albumen paper, beneath the negative in the usual way, and, when sufficiently printed, let it be carefully washed in the dark room, so as to remove all the free nitrate of silver, &c. Now immerse it in the following solution, also in the dark room:—Saturated solution bichloride of mercury (corrosive sublimate), 1 ounce; hydrochloric acid, 1 drachm. The saturated solution is previously prepared by putting into water more bichloride of mercury than it will dissolve by shaking in about twelve hours.

The print will gradually be bleached in this liquid, in the ordinary meaning of the word—that is, it will disappear; but the fact is, the print is still there—its colour alone is changed, a double salt having been formed of mercury and silver, which is white, as many of our readers, who have been in the habit of intensifying with a mercurial salt, are aware of. As soon as the print has quite disappeared, the paper is thoroughly washed and dried in the dark room; it is also preserved between folds of orange-coloured paper, in order to keep it from the action of light, for the surface is still in some measure sensitive to light.

The bleaching of the print—that is, its conversion into a white salt—is effected more quickly by keeping it in motion in the mercurial solution.

As we said before, the print has not been bleached in reality—the substance which originally formed it is still there, together with a new substance, a salt of mercury. But the two salts of silver and mercury may be easily brought out and made visible by several solutions, such as sulphide of ammonium, solution of hydrosulphuric acid; in fact, any of the soluble sulphides, ammonia and hyposulphite of soda. The latter salt is used in preference to the others. Small pieces of blotting-paper, therefore, of the same size as the prints, are cut out, and steeped in a saturated solution of hyposulphite of soda, and then dried.

The magic photographs are packed, as before stated, between folds of orange-coloured paper; the papers dipped in hyposulphite of soda are the developers, and may be packed between two sheets of common writing-paper. The development of the image is effected in the following manner:—Place the albumen paper which contains the whitened print on a pane of glass, print side upwards; on this lay the dry piece of blotting-paper that has been previously dipped in hyposulphite of soda. Moisten the latter thoroughly, then place over it a pane of glass, and upon this a weight, to bring the two pieces of paper into intimate contact. In a very short time the picture will appear in all its original detail, and of a sepia tone.

Mercury-Gilding.

Although mercury-gilding is not much practised now-a-days, yet as a great portion of its processes were starting-points in electro-chemical manufacture, some details of the method may prove useful.

The nature of the copper alloy operated upon has a great influence upon the success of the gilding. The alloy recognised as the best by M. Darcet, who so greatly ameliorated this murderous art, is composed of copper 82 parts, zinc 18, tin 1, and lead 8 parts; a smaller proportion of copper leads to accidents in the success of the gilding. The mercury serves as a medium in the gilding by forming a double amalgam of copper and gold; it is, therefore, important to take the alloy richest in copper, for the heatings employed to prepare the metals for being cleaned are for the special object of bringing the external surfaces to the state of pure copper by the volatilisation of the zinc, and consequently facilitate the combination of the amalgam with the copper surfaces. The operations in mercury-gilding are "scraping and cleaning;" "gilding" including the preparation of the amalgam, its application to the pieces to be gilt, and the volatilisation of the mercury; and the "colouring," including "matting," the putting on "red gold," or *ormolu*, and burnishing. The cleaning processes have been described in our articles on "Electrotyping."

Gilding.—For mercury-gilding, fine gold—that is, gold at 1000—is useless, it dissolves so badly; an alloy of gold and copper, of $\frac{960}{1000}$ths at least, must be employed. To prepare the amalgam, put into a crucible, heated upon a well-ventilated gilder's forge, 1 oz. of gold and 7½ oz. of mercury; then, with a hook of coarse iron wire, stir up the gold and mercury from the bottom of the crucible in order to facilitate the solution. The amalgam formed is poured out into an earthen basin, and kneaded with the hand so as to squeeze out the excess of mercury; it must be pasty, like modelling wax, and retain the imprint of the fingers; it contains 9 to 11 parts gold to 91 to 89 mercury; it is then divided by the hand into four, five, or six pieces or more, according to the size of the articles to which it is to be applied. The quantity of gold in each piece may be easily estimated.

The gold thus amalgamated is now placed upon an unglazed earthen plate; then, with a scratch brush, made in the shape of a very fine pencil, and dipped into a solution of nitrate of mercury diluted to $\frac{1}{10}$th or $\frac{1}{50}$th, according to the richness of the copper, the article is rubbed, with as little amalgam as possible also, until it becomes whitened. This done, the amalgam is laid on according to the thickness of the coating it is wished to be deposited, by brushing with a gentle stippling action, with the point of the scratch-brush, until the coating is uniform throughout.

Firing.—The articles are next heated over a brisk fire. From time to time a drop of water is thrown upon the gilded article; when it frizzles, it is withdrawn from the fire with a pair of tongs, held in the left hand, protected by a stout leather glove against burns and contact of mercurial fumes, then, with a long-handled brush, held in the right hand, we tap the surface, in order to extend and equalise the gold. This operation being repeated upon the article five or six times, we perceive that the mercury has evaporated, and the article has become of a straw-yellow colour.

It almost always happens that the gold has not taken sufficiently everywhere; then the operation has to be partially gone over again—not with the nitrate of mercury, but with water acidulated with nitric acid. The gold amalgam is then placed upon the weak parts, but with a smaller scratch-brush; the article is next fired, to volatilise the mercury, and afterwards "scratched" under water slightly acidulated with vinegar, or with liquorice-water, then passed through warm water, and dried in sawdust. The scratch-brush gives the gold a greenish tinge, and a very uniform brilliancy in all those parts over which the scratch-brush has passed—a sure sign that the work is finished.

Colouring.—To give the commercial aspect to the gilding, after the scratch-brush recourse is had to colouring. That most employed is *ormolu*.

First, the article is heated, when it takes a stronger straw-colour; it is then allowed to cool, and *ormolu* colour is applied with the pencil. Heated to a brown fusion point, the article is immersed in water containing five per cent. of hydrochloric acid. It is then washed with a pencil, and dried. The desired colour being obtained, the smooth parts are burnished with stone or steel tools, then slightly warmed and dried, and the article is finished.

Matting.—This process demands much skill and experience. After the scratch-brushing, the parts not gilt, or which are to be burnished, are covered by means of a soft pencil with a mixture of Spanish white, well ground up with weak gum and sugar water. The article is left to dry before the fire, and then attached by an iron wire to a piece of flat iron called a *mandrin*, taking care not to put the attachments on the parts which are to become *mat*. The article is then heated over a charcoal fire until the gilt parts become blue; then, by means of a pencil, it is covered with a composition called *mat*, which is melted in an enamelled iron saucepan. This composition consists of—water, 5 parts; nitrate of potassa, 46 parts; potash alum, 46 parts; and sea salt, 3 parts.

The article, covered two or three times with this mixture, is heated until the salts melt, and become golden-yellow while becoming detached from the surface; it is then quickly immersed in a large cistern of water. The detached salts fall to the bottom of the cistern, and the article appears of a beautiful gold *mat* colour. In this operation, the *mat* is due to the surface being attacked by the disengagement of chloride, which, dissolving the copper of the alloy, forms a fine network, and, by not reflecting the light, produces the *mat* effect.

The portion of the article opposite to that first immersed almost always shows green spots. The article is returned to the fire; then, with a pencil and the *mat* mixture, diluted with a little water, the spots are carefully gone over. After heating a few minutes, it is re-dipped in the cistern, then washed in water very slightly acidulated with nitric acid, rinsed in warm water, and dried in an oven.

The portions covered with Spanish white are burnished in the usual manner; the article is then washed, dried, and carried to the *mat* furnace, and finally dried, to avoid the appearance of spots of mercury.

The process for obtaining red gold has been described in the articles on "Electrotyping." To be applied successfully, these processes imperatively demand a determined quantity of gold, without which success is impossible. Thus an article which may be gilt by the battery with 25 gr. of gold requires 50 gr. when gilt with mercury and *ormolu*, and 1 gr. for the *mat* gilding.

Strength of Glass.—The tensile breaking strength of annealed flint glass is about 2,286 lb. per square inch, or 1·02 tons; of green glass, 1·29 tons; and of crown glass, 1·14 tons.

A Sure Test for Kerosene Oil.—*Good* kerosene is not explosive to any dangerous degree whatever; it is only when it has an excess of benzine or some other explosive substance that it becomes dangerous. The following test is given, as showing the difference between oil sufficiently pure to be safe, and that which is otherwise:—Fill a tumbler three-fourths full of moderately cool water, and pour one-half of a tablespoonful of oil on to it; stir it together, then hold a lighted match over it, and if it takes fire from the vapour before the flame comes in contact with the oil, it is dangerous and ought not to be used, as good oil will not thus ignite, and will not burn readily even when a lighted match is thrown into it, but most of the adulterated oil will burn freely.

Some exceptional instances of retention of mental vigour in old age have been recently occupying a share of public attention; and *apropos* of a letter of Dr. Forbes Winslow's on the subject, it has been remarked as an undeniable fact that a large number of the noblest works of the imagination have been produced when their authors had reached the period when it is generally supposed that the faculties begin to decay. Michael Angelo began his great picture of the "Last Judgment" when he was fifty-nine. Milton finished "Paradise Lost" when he was fifty-seven. Among musicians the facts are fully as remarkable. Gluck revolutionised the operatic art by bringing out "Orfeo" when he was fifty. Handel was fifty-eight when he wrote his "Esther; when he wrote "Israel in Egypt" he was sixty-five; and when he wrote the "Messiah" he was sixty-seven. Haydn wrote the "Creation" when he was sixty-four, and Beethoven was fifty-three when he wrote the "Choral Symphony."

AN INTELLECTUAL PUBLIC-HOUSE.

The new building recently erected for the Hulme (Manchester) Free Library has just been opened with some *éclat*. It is a handsome structure, in the Italian style of architecture, and contains, on the ground floor, a vestibule, library, and news-room, the library being 48 ft. 9 in. by 29 ft. 6 in., and the reading or news-room 47 ft. 6 in. by 42 ft. 9 in. The latter is most admirably adapted to the purpose, being very light, and well ventilated. It is fitted up with the usual stands, tables, &c., and well supplied with the leading papers of the day. There are from 10,000 to 11,000 volumes in the library, about 1,000 having been very recently added, chiefly books of reference, it being intended to accommodate visitors with such books for reading in the news-room, in addition to those in the lending department. The front part of the building is three storeys high, the second consisting of a committee-room and lavatories, over which is a store-room. The cost of the building was a little over £3,000.

The first branch library in Manchester was established in Hulme. In the first year of its being opened, when the books were located in a comparatively small house on this side of the road, and not very far from the room in which they were assembled, 215 volumes per day were issued, making, during the year, an aggregate of 50,000 volumes. 50,000 volumes were read during the first year of the library being established, though that year had comprised only 233 days, for the report of the free libraries has always been made up to the end of September, and that report was made up to the month of September in that year. In the second year of its establishment 226 volumes per day were issued, or an aggregate of 67,000 per year. In the third year of its establishment the daily issue was 231, the aggregate issue for the year upwards of 69,000. In the fourth year the daily issue was 259, the aggregate for the year being 77,000 and upwards. In the fifth year the daily issue was 305 volumes, and the yearly aggregate upwards of 91,000. In the sixth year the daily issue was 319, and the aggregate issue close upon 96,000. In the seventh year the daily issue was 296, and the aggregate during the year 89,000. During the last year, ending September, 1865, the daily issue was 318, and the aggregate for the year nearly 96,000 volumes.

Some time ago it was suggested that a complete set of the Holy Scriptures, printed in embossed characters, should be provided in the Manchester Free Libraries for the use of the blind. The cost was considerable, but the committee incurred the cost, and divided the books amongst the branch libraries, so that in every branch may now be found some portion of the Holy Scriptures, which the blind can have by applying for. The result has been in every way satisfactory, and the books have proved a source of comfort to those who were comparatively shut out from society by the loss of sight. The general character of the society may be gleaned by a few statistics of the classification. On theology and philosophy there are 187 volumes; history, biography, voyages, and travels, 1,900; politics, commerce, &c., 87; science and arts, 510; general literature, 3,730; and books for the blind, 20. Well may the working men of Hulme feel proud of their new institution. We wish there were more such "public"-houses.

FLOWERS FOR PERFUMERY.

The number of flowers used for perfumery purposes has hitherto been limited to seven, viz., rose, jasmine, orange, violet, jonquil, tuberose, and cassie. The rose used is the hundred-leaved rose (*Rosa centifolia*), the jasmine is the *Jasminum grandiflorum*, the orange is the bitter orange (*Citrus bigaradia*), and the violet the *Viola odorata*, or double Parma violet.

The tuberose (*Polyanthes tuberosa*) and the jonquil (*Narcissus jonquila*) are two bulbous plants, and the cassie (*Acacia farnesiana*) a pretty shrub with globular golden flowers, which thrives admirably in the south of France.

Out of those flowers four only are distilled and yield essential oils, viz., rose, orange, jasmine, and cassie. Rose gives the far-famed otto, which is principally made in Turkey, near Adrianople. Orange flowers produce what is called neroly, a name derived from *nero olio*, dark oil, on account of its becoming dark by exposure to light, and not, as some people have imagined, from its having been discovered in the time of Nero, for the Romans were totally ignorant of the art of distillation. Jasmine and cassie are only distilled, to my knowledge, in Northern Africa (Algeria and Tunis) and in India, European flowers not possessing a sufficiently intense fragrance.

The aroma of the other flowers is extracted by means of absorption or maceration. Besides the flowers named, others are sometimes submitted to these processes, such as mignonette, lilac, hawthorn, wallflower, lily, heliotrope, sweet-pea, &c.; but the quantities obtained are so small, that they have hitherto been mere experiments, and we are still obliged to compound all these perfumes artificially by studying resemblances and affinities, and blending the shades of scent as a painter does the colours on his palette. Thus, for instance, we imitate heliotrope with the aid of vanilla, sweet-pea by a mixture of rose and orange flowers, magnolia with tuberose, orange flower, and a dash of lemon, &c.—*Eugene Rimmel.*

Facts and Memoranda.

The cultivation of tea in India is a great success. The Government factory turned out 16,125 lb. last season.

The flexibility of "spun" glass is so great that it has been proposed to use glass fibres as a textile material for articles of clothing.

It is proposed in California to supply San Francisco and a dozen interior towns with water from Lake Tahoe. The length of the aqueduct, if it is extended to San Francisco, will be 200 miles.

The Cobden railway station, on the Illinois Central Railroad, about twenty miles from Chicago, is the chief depôt for the produce of numerous fruit farms in the surrounding country. From seven to twenty tons of strawberries are sent daily from these farms to supply the markets of the north. Eight years ago these farms were portions of the primitive forest.

Society of Arts' Examinations.—The Prince Consort's Prize of twenty-five guineas has been awarded to Mr. James Rigby Smith, aged twenty-five, of the City of London College, clerk, who has obtained the following first-class certificates:—Political economy, first-class certificate; arithmetic, ditto; geometry, ditto; book-keeping, ditto; algebra, ditto, with second prize; logic and mental science, ditto; domestic economy, ditto.

Coal in Germany.—The total amount of coal produced in the States of the German Zollverein in 1864 was 388,179,637 cwt. Of this Prussia produced 330,954,892 cwt.; Bavaria, 4,888,817; Saxony, 42,182,202; Hanover, 6,890,671; Baden, 246,772; Electoral Hesse, 2,926,638; Thuringia, 89,595; and Oldenburg, 50. The total amount produced in 1864 was 50,045,485 cwt. more than in 1863.

Cotton Manufactures in Mexico.—In Mexico there is a large cotton manufactory, conducted by Senor Don Grandison, an American. It is situated at Cocolapam, and employs from 300 to 400 hands. Senor Grandison manufactures all kinds of cotton and some woollen goods, and the articles he produces are much appreciated and sought after by the natives, both Indian and Mexican. The machinery of the mill is worked by water-power derived from a river that passes through the town.

Oiling Leather.—The *Scientific American* says that oils should not be applied to dry leather, as they would invariably injure it. If you wish to oil a harness, wet it over night, cover it with a blanket, and in the morning it will be dry and supple; then apply neat's-foot oil in small quantities, and with so much elbow grease as will ensure its disseminating itself throughout the leather. A soft, pliant harness is easy to handle, and lasts longer than a neglected one. Never use vegetable oils on leather; and among animal oils, neat's-foot is the best.

Petroleum in Shropshire.—An American gentleman, Mr. Holmes, who has had considerable experience of the oil fields of Pennsylvania, and is now superintending some very large coal-distilling works recently established at Ruabon, is so convinced that large stores of natural petroleum exist in Shropshire that he is making arrangements for the erection, on the estate of Lord Forester, of proper machinery for putting the matter to a decisive test. All, indeed, that remains to be tested is as to the quantity in which oily and pitchy bodies occur in the district in question, for that they do occur there is matter of experience. An oily liquid is frequently found oozing through the rock through which the shafts of the mines in the Coalbrookdale coal field are carried, and often occasions considerable annoyance to the miners. "Tar Tunnel," Benthall, and "Pitch Yard," Coalport, received their names from the occurrence in them of a substance which was at one time collected in considerable quantity, and sold as "Betton's British Oil." These are but a few out of many similar facts, all suggesting the probability—the almost certainty, Mr. Holmes thinks—of the existence of a considerable oil field in Shropshire.

New Iron-Preserving Agent.—Dr. Henry Edward Francis De Brion, a Parisian physician, who for many years has resided in England, has discovered and patented a process for preparing from india-rubber what we may designate an *enamel paint*, which is absolutely proof against the action of the atmosphere, as well as against the power of all liquids (including the most potent acids) to affect iron. This enamel paint possesses all the remarkable qualities of india-rubber, without combining with them any other substance or element that is calculated in the slightest degree to counteract their thoroughly efficient operation. The preparation is applied cold and in a liquid state, and in consistency and general appearance it resembles such common oil-paint as is ordinarily used for ironwork. It may be applied with ease; but of course it is necessary that the process of application should be conducted with such care as will ensure a complete covering of the surfaces to be protected. This covering may be so thin that its presence cannot be detected; while it leaves the protected surfaces in all their original sharply-defined freshness. It hardens also at once, and immediately forms a smooth and lustrous enamel-like covering, air-proof, damp-proof, water-proof, and acid-proof. Thus protected, the iron is safe. Rust cannot accumulate upon the surface of this enamel paint, nor corrode beneath it. —*Art Journal.*

Our Next Number.

WITH our next number will commence the new Penny Series, of which we have apprised our readers. Former periodicals addressed to the working classes have been entirely literary, and not very relevant in their information; or purely scientific, and lacking general interest; or mechanical, to the exclusion of social topics. We intend to supply literary information that shall be relevant to the wants and curiosity of the day; to report facts of scientific progress which have interest to all; to add to mechanical and industrial knowledge accounts of the chief social topics which now constitute the modern life of the people, and introduce a fresh feature, unattempted in the days when the Society for the Diffusion of Useful Knowledge reigned—namely, the discussion of public affairs and political questions affecting the working man as a citizen. The want of this living information, if we may so call it, has long been felt. The working class has not only increased in numbers and intelligence, but the range of questions in which they take interest has grown also. Now-a-days a man is not merely an artisan, he is a citizen—a trades unionist—a politician; he cares for personal improvement and for public affairs. Our aim is to supply information not elsewhere to be found, and a paper which, if not indispensable to working men, shall have features of wide interest to them, and of direct and daily utility.

With our next number will be given to each reader a large Map of Europe, to illustrate the seat of the new European war. Explanatory articles will also appear in these columns, furnishing full, clear, and reliable information on the origin, character, and tendencies of the war as respects the future of the working classes of the Continental nations.

The communications we have received assure us beyond a doubt of the active good wishes of our numerous subscribers.

In this number, therefore, we have ventured to enclose a sheet of small bills announcing the features of our New Series, and we believe that each reader will be glad to do us the service of cutting up the sheet, and distributing the parts among friends and acquaintances.

Public Topics.

AN eloquent preacher, who had had great experience of life, once said, "Error always dies game." It is ubiquitous. It is like Sir Boyle Roche's bird—it is in two places at once, and somewhere else also. A misrepresentation is always long-lived. It seems to have no mortal place. It is like a worm alive at both ends. If you cut it in two, each separate part wriggles on its own account, and all you can do is to chop at it. A distinguished French historian has found out the truth of this. M. Louis Blanc was the most brilliant of modern advocates of the organisation of labour, to which every day brings us nearer. During the French Revolution of 1848, he promoted plans of Industrial Associations, when some clever opponents set on foot a burlesque of his plans, called "National Workshops," on principles so wild and absurd that they must come to grief. These plans were imputed to M. Blanc, and no human ingenuity has ever been able to correct the skilful misrepresentation. Once or twice every year since, has this imposition been denied, refuted, contradicted, proved to be false. It has been done in public speeches, in books of history, in pamphlets, in reviews, in newspapers—all in vain. Nothing can touch the vitality of the imposition. The other day the *Standard* repeated it in its French correspondent's letter. Even in the very city where the falsity of the report is best known, it is repeated as vehemently as here, where there is excuse for ignorance of foreign affairs. This misrepresentation of the character of the proposals for the organisation of labour in Paris in 1848, is of very great importance to the working classes everywhere. It has arrested the progress of this great question, prejudiced people against it, turned friends aside from it; it is, therefore, of interest to hear what the author of the movement traduced really had to do in the matter. Louis Blanc was an eminent historian in his own country, before he became an exile in ours. He has since attained a high literary reputation in this country, as a most intelligent, impartial, and best-informed critic of English political institutions which the French nation has ever sent us. His own words, therefore, in vindication of himself, deserve quotation in these columns. They are:—

> I most emphatically deny having had anything whatever to do either with the establishment or the organisation of the national workshops in 1848, and it surprises me to the utmost that writers supposed to be well informed should still be found to fasten upon me a charge the falsity of which has been made patent by my writings, my speeches, and my acts; by a series of official documents inserted in the *Moniteur;* by the evidence adduced before the commission of inquiry which the National Assembly appointed in 1848; by the declarations of the members of the Provisional Government; by my public and repeated denials, never contradicted, of any connection whatever with those national workshops; by the confessions of their real contrivers, and of their very director, M. Emile Thomas. In 1848 the national workshops were *not* started by me. Nay, they were established in hostility to my principles, and for the express purpose of opposing my influence. Their object was, as formally stated by M. Emile Thomas, in his "Histoire des Ateliers Nationaux," "to set up an altar opposed to that of the Luxembourg." The following is the declaration of M. de Lamartine, in his "Histoire de la Révolution de Février"—"So far from being in the pay of Louis Blanc, as has been said, the national workshops were the device of his adversaries."

If there be any dash of mortality in this misrepresention, it will die of this exposure. It will be well if some moral rinderpest could break out among errors and carry them off, after the manner of the cattle plague. No bill will ever be proposed in Parliament to arrest so serviceable an epidemic.

EVEN the interest of the rising European war has been superseded by the sudden fall of the Government. We say sudden, because its end came in an incidental kind of way. We may have had an honest Government before in England, but this is the first Government which the nation knew to be honest. The usual end of a Government is a great party fight, in which hostile leaders, bearing openly public standards of battle, meet in deadly conflict, and defeat wears an air of Titanic strife and grandeur. But in this case a shabby, Janus-faced "amendment," looking two ways at once, but never in the face of the foe, borne by an Irish knight, issuing from the Cave of Adullam, took, by a cowardly stratagem, the destiny of the nation into its hands—into hands not able to hold them. The Government had proposed, as our readers are aware, a £7 franchise, which would admit some 240,000 new electors into the constituencies. Instead of a rental franchise, Lord Dunkellin proposed a rating franchise, the effect of which would be to convert the £7 into a £9 franchise, which would add to the constituencies scarcely 45,000 voters. The Government resisted this proposal, which was carried by a majority of eleven. Mr. Gladstone was not met by a direct proposal to reject a £7 franchise, but by an underhand motion to adopt a different plan of estimating the franchise, which would defeat it without assuming to defeat it; so that members may say to their constituents that they did not oppose Reform at the same time that they voted for a method of reform which would effectually defeat it.

No great party speeches preceded the division. The night might be characterised as one of wrangle and riot, interspersed by a very few explanatory speeches. The Opposition were more rude and turbulent than usual. On Tuesday night the House and lobbies were crowded. Mr. Gladstone, in a few sad and cold words, simply announced that, from the character of the division which had taken place early that morning, the Ministers of the Crown had thought it their duty to communicate with Her Majesty, and might, by the next Monday, be able to state the result to the House. The Queen being at Balmoral, Earl Russell would have to proceed to Scotland, to confer upon the course which the Crown should advise. Mr. Gladstone's announcement was received in silence. The responsibility which the Opposition had incurred in plunging the country into political uncertainty, in the face of a European war, was no matter for exultation.

THE question was lately discussed in our Legislature, whether intelligence carried with it any political guarantee? It has hardly been settled in this country whether ordinary education, of the mere intellectual kind, carries with it moralising influences. In America the question is considered pretty much as settled, and they accept as authority upon the subject the results arrived at in this country. In a State paper recently published by the United States Government on "Prisons and their Discipline," there is quoted with satisfaction

and approval the opinion of Mr. C. P. Measor, an officer at the Chatham prison, England, which might serve to set at rest the disputed question as to the actual influence of mere education for the repression of crime. His words, so precise and decisive, are entitled to special consideration :—

It would seem (says he) that the evidence furnished of education, among even the criminals themselves, tends to show that the small amount of instruction implied in the test here recognised—the simple distinction between the ability to read and write imperfectly, and inability either to read or write at all—has a most material influence in the development of crime; and, were the investigation carried no further, we should be forced to conclude that, since the most criminal districts show a higher ratio of uninstructed persons among the criminals, and the less criminal districts a less proportion who are wholly destitute of the rudest elements of education, the immediate inference is, that even this small degree of instruction tends to the repression of crime.

When Mr. Gladstone consented to hamper his Franchise Bill with one for the Redistribution of Seats, the fall of his Government was sealed. His conciliation has been futile. Nothing would conciliate the Opposition but withdrawing the Bill. To ask the House to reduce the figure of £7 to £5, and so restore the balance of the suffrage to the amount fixed by the Government, would be to ask the Opposition to kick them out, not having themselves the quickness of insight necessary to tell them when to go. While these pages are travelling to our readers, Her Majesty will have returned to Windsor, for the purpose of consulting with her ministers whether Earl Russell or Lord Derby shall hold the reins of power. In the meantime, all who care for Reform have due notice to bestir themselves. If they intend to have the question settled, and not shelved for years, meetings must be held in support of the Gladstone Government. The people never had a minister before who cared for *them* as Mr. Gladstone has done. The question is, Do they care for *him?*

The Artist Workman.

SHIELD OF THE SIXTEENTH CENTURY.

This shield is carved in wood, and is supposed to be the work of an Italian artist. According to all appearance, it has served to adorn one of the splendid festivals which the princes of the Italian cities lavished on the people in the course of the sixteenth century, and in which enormous triumphal cars promenaded the squares and principal streets, performing pompous scenes, the subjects of which were derived from the mythology or ancient history of Greece and Rome. Doubtless, the buckler, or shield, represented in our engraving was a portion of the arms of some young nobleman of Pisa or Florence, representing a Roman Emperor returning from his victories. The arabesques of the border are remarkable for their richness. This piece of carving may be considered as a valuable example of Italian taste at the best period of the renaissance.

SHIELD OF THE SIXTEENTH CENTURY.

Primrose Hill.

When I was a little boy, now "ever so long ago," Primrose Hill was in the country indeed. The Regent's Park was formed, but the trees were little saplings, and there were no flower-beds. The York and Albany and Park Street were the limits of the houses, and from Gloucester Gate to St. John's Wood there was nothing but open fields, thick patches of woodland, and hedgerows, with tall elms and decaying stumps of oaks I don't know how many hundreds of years old. The hill itself had no paths, no cricket-ground, no pavilion, and there was no gymnasium or Shakespeare's Oak in the fields at the foot. We used to run up and down the slopes, pick up buttercups and daisies, scramble through hedges, climb stiles (swing-gates we knew nothing about), jump ditches, and altogether enjoy ourselves, as much out of the sight of houses as if we were in the midst of Salisbury Plain. Old Chalk Farm, indeed, there was; but it was a small, irregularly-built white house, with what we called a "tea-garden," though tea was certainly not the most favoured beverage. The top of the hill was worn bare—as, indeed, it is now—by the tread of many feet; and I cannot say much for the decorum of the proceedings there on high-days and holidays; and perhaps it is quite as well that there are now park-keepers to preserve a little better order.

But what a view we had from the summit! and didn't we think we had achieved something little short of Alpine climbing when we got there. If we looked towards the Regent's Park, there it lay below us like a picture. The outer road, of horse-shoe shape, the inner circle, the lake, the broad paths so clean and new, like long pine-shavings stretched across the green sward, and dotted with the moving figures of men and women and children; the plantations and the mansions scattered about, and the animal-houses and rustic lodges of the Zoological Gardens—all were clear and distinct in the bright sunshine. Beyond rose the extinguisher-like spire of the Langham Place church, the dome of the London University, the dense mass of houses, distinct enough in the foreground, but blurred and misty with increasing distance, and the hundred steeples of great London, with the crowning dome and towers of St. Paul's standing out in massive strength and beauty against the sky.

When we turned round, there were Hampstead and Highgate, the small tower and weathercock of the church at the former place peeping above the thick foliage, and Highgate church, white and new, the most prominent feature in the landscape. The fields between us and the Hampstead hills were, I verily believed then, the pleasantest in existence; and, though I have seen a great deal of the beauty of English landscape since, I am almost disposed to think so now. The grounds of old Belsize House, regarding which I could relate some singular anecdotes, were enclosed in massive red brick walls, and there was a long narrow passage through the grounds, "a place for whispering lovers made." A friend of mine, who has read almost more books than I have ever seen, says that John Keats, Leigh Hunt, and other writers who seem quite familiar to him, though I hardly know their names, used to stroll about these Hampstead fields and write poetry about them, and that, in consequence, they were sneered at by other writers—who used to climb mountains, and row about on foreign lakes, and were familiar with all sorts of grand and beautiful sights—as the "Cockney poets." It would take a great deal to make me a poet (indeed, I don't even know many songs, which I suppose are poetry, though now and then I hum "Through the wood, laddie," just by way of a joke, when I am cutting up a plank of inch stuff); but, upon my word, sometimes when I have been lying on the long grass in those Hampstead fields, and felt the sweet wind come trembling, as it were, over my face, and heard the skylark singing ever so high up, I have had a sort of feeling that I can well understand a cleverer fellow than myself might turn into very good poetry.

But it's of no use talking about old times like that. I dare say, mother, that young Willie and Jenny there, who are cutting all sorts of capers on the grass, are quite as happy as we were when we used to race down hill for a cake; and it doesn't signify much to them that the hill is now railed in and called a park—that railway trains are puffing and blowing in a cutting just below us—that houses have crept up on every side—that, though we can see Hampstead and Highgate still, yet all between us are roofs and chimney-pots, terraces, Adelaide Roads, Belsize Park Estates, shops, and big taverns where Chalk Farm used to be, and railway stations and huge circular engine-shops and stables, where you and I used to run after the bright-coloured butterflies, and pick up daisies and all sorts of little wild flowers to put in bottles on the mantelpiece at home.

We used to play at leap-frog and fly-the-garter when I was a boy, and I could fly eight or nine

feet as well as the best of them; but we never could do such wonderful things as these young fellows are doing now in the gymnasium. Those parallel bars would beat me now altogether; so would the trapeze and vaulting on the wooden horse; and shouldn't I be giddy swinging round and round with those ropes! But the young fellows like it; and it's a good thing to bring out the muscles and open the chest, and prevent a fellow being round-shouldered and weak-legged and stunted.

Yes, if you like, mother, the children shall have a bun and a bottle of ginger-beer at Marioni's, in the Pavilion; and then we will look at the cricketing. It is a queer ground, all on a hill-side; but it will do for practice. There they are, big and little—school clubs with coloured caps, boys who belong to no club at all—small chaps in knickerbockers, big ones in flannel trousers—soldiers with their jackets off bowling and batting away like fun. That's a good one for a four, right away to the garden walls of the houses in the Avenue Road; and that's a good one, too, my little man, right over Willie's head, and almost knocked mother's bonnet off.

Now, we will go to the top of the hill. The sun is setting behind Kilburn, the shadows are getting very long, the perambulators are on the move, the little crowd listening to the soldier who is preaching—there are preaching and praying soldiers now, as there were among Cromwell's Ironsides or Havelock's regiment—are beginning to disperse; and when we have rested a little, we must make our way home. I like Primrose Hill, that's a fact, and you shall come again, Willie and Jenny, and have another run.

WORK! WORK!

From the sea the tireless sun
Mounts, his daily course to run;
Month by month the moon on high
Circles o'er the midnight sky;
Rivers with unresting sweep
Still roll onwards to the deep;
Trees and plants, with foliage fair,
Fan and cool the summer air;
All things work, and thus fulfil
Their all-wise Creator's will.

Thou for whom the sun was born,
Whose is the rich glow of morn,
And the moon's soft gleaming light
Silvering the dark face of night;
Thou for whom God bade the earth
Give to flowers and forests birth;
Thou for whom, with her rich hoard,
Was earth's labouring bosom stored;
Thou of all God's works the latest,
Likest unto him and greatest;
Thou, whose life *beneath* the sky
Like a short dream passeth by,
But whose life *beyond* must be
Lasting as eternity;
Wilt thou live in listless sloth?
Wilt thou, like a heedless moth,
Flit round pleasure's flickering flame,
Till, self-scorch'd, thou sink'st in shame?
Shall each precious God-sent day
Pass in tattling, trifling pl y?

Loiterer, gird thee for thy race!
Flinching soul, thy conflict face!
God thy work to thee has given;
Work in faith—then rest in heaven.

—*Selected.*

Growth of Cotton Manufacturing in America.—In the year 1860 the cotton crop of the United States was 5,000,000 bales. Of this amount 1,094,752 bales, or more than one-fifth of the aggregate, was consumed in the manufactures of the country. It will be seen, therefore, that we have made much more actual progress in this business than has been generally known. The growth of the cotton manufacture at home may be seen by the following figures:—In 1791, 5,500,000 lb.; 1801, 9,000,000 lb.; 1811, 17,000,000 lb.; 1821, 50,000,000 lb.; 1831, 77,500,000 lb.; 1841, 97,500,000 lb.; 1850, 245,250,000 lb.; 1860, 422,704,975 lb. This progress has been both steady and remarkable, and it shows that the protection heretofore afforded to this branch of industry has proved serviceable in fostering the business and setting it forward in the direction of permanence. It is not too much to say that these figures are sufficient to warrant us in looking forward confidently to a period, not remote by any means, when the whole cotton crop of America will go into our own home factories, and be there made up into goods for use. If the home factories took one-fifth of the entire crop of 1860, we may safely state that by 1870 our enormously increased capital and resources will enable us to double our manufacturing capacity in that line.—*Philadelphia Paper.*

*Government Life Insurance.**

In our last article we stated our belief that the rates of premium charged by the Government were lower than those charged by private offices, and we have been favoured with the necessary facts for establishing that assertion.

Here is a comparative view of the annual premium to insure £100 charged by those offices which have the largest connection amongst insurers for policies of small amount:—

Age next Birthday.	Government Insurance Act.	Friend-in-Need Society.	United Brothers' Society.	Victoria Benefit Society.	United Kingdom Provident Institution (with Profits).
21	1 17 11	2 5 8	2 3 0	1 19 2	1 18 4
26	2 1 11	2 10 9	2 7 0	2 4 5	2 3 10
31	2 7 10	2 15 8	2 15 0	2 10 7	2 10 0
36	2 15 4	3 3 0	3 5 0	2 18 2	2 17 6

The advantages here are clearly all in favour of the Government insurers; and if we take the form of insurance wherein the premiums are payable by monthly instalments, we shall see a wider difference yet:—

Age next Birthday.	Government Insurance Act.	Friend-in-Need Society.	British Prudential Society.	United Brothers' Society.
	Premium of 24s. a Year, Payable by Monthly Instalments.	Premium of 26s. a Year, Payable by Monthly Instalments.		
21	58 0 6	47 2 0	48 6 0	41 8 0
26	51 5 4	42 12 0	41 14 0	38 14 0
31	44 16 6	38 2 0	35 8 0	36 0 0

Thus a person, aged 21, insured in the Government office, secures £58 for 24s. a year, whilst in the United Brothers' Society he would only get £41 for 26s. a year—a difference on the wrong side of £17, even if the premiums were the same.

Such facts as these ought to open the eyes of the shrewd, practical, working men who, in a general way, are not slow to perceive in which direction their true interests lie.

And we must reiterate that these comparisons are still further heightened in favour of the Government office, by the perfect security, by the enjoyment of right to benefit *directly the first premium is paid*, and by the *immediate* payment, on proof of death, of the sum insured.

So far, our observations have had exclusive reference to that kind of provident investment which is made for the benefit of those we leave behind us when our part in the battle of life is ended, and one of

"Death's thousand doors stand open"

for our departure. But many desire to anticipate the period of life when their energies may be expected to fail as their need of comforts increases, and out of the abundance of to-day to set aside somewhat for the insufficiency of to-morrow. This can be done by purchasing an Annuity, or annual sum, to be paid regularly to the annuitant as soon as a given time has expired. Thus a man, by paying small sums out of his earnings while he is strong, active, and in full work, may secure for himself an annuity, to commence as old age comes on him, and which will take the place of his wages or salary when he can no longer earn a livelihood.

We have already specified the different ways in which life annuities are obtainable. An *immediate* annuity is an annual sum payable to the purchaser, commencing immediately after the purchase, in consideration of a premium, which is paid in one lump sum. A *deferred* annuity, on the contrary, is an annual sum payable to the purchaser, which is not to commence until after the expiration of a specified term of years, and it may be purchased either by a single premium, or by an annual premium extending over the term before the annuity is payable. Another very excellent provision is that of the *deferred monthly allowance*, which is a sum payable every month to the purchaser, commencing on the expiration of a given number of years, and the purchase money may be paid by monthly instalments, during the period before the monthly allowance becomes payable. Two different rates of premium, or purchase money, as it is usually called when relating to annuities, have been framed, one of which provides for the return of the purchase money in the event of death before the annuity or allowance commences, or if the purchaser wishes to put an end to the contract. Of course the rates on this plan are higher than when no such condition is stipulated for.

In the case of annuities, as in life insurances, purchasers may begin with the minimum amount purchasable, and may increase it as their circumstances will allow. Husband and wife are looked upon as two distinct persons (for the purposes of this Act, we mean, of course), and may separately take the full benefit of the maximum limits of provision granted by the Act.

The tables relating to annuities would occupy too much space for us to print even portions of them, but they may readily be obtained, with all necessary information on the subject, through any post-office.

It only remains for us to give such a brief outline of the *modus operandi* as may be useful to any of our readers who may be induced to follow the advice, which we very earnestly tender to them, to register their names as speedily as possible on the Postmaster-General's good books.

The benefits of life insurance may thus now be obtained through the Post-office without difficulty, and in the following manner:—

1. A person who desires his life to be insured by the Postmaster-General, should apply for a form of proposal at any one of the post-offices which have been opened for insurance business. He can ascertain at any post-office, during the hours appointed for the transaction of Money Order business, the names of those post-offices which have been opened for insurance.

2. The proposal form should be filled up by him, or by some one on his behalf, and he can take it away from the post-office to his own home or place of business for that purpose. He will have to state his name, trade, calling, or occupation, where he lives, where he was born, the date of his birth, the sum for which he wishes to insure, and the manner in which he proposes to pay for the insurance. Instructions for filling up the form are printed thereon.

3. He will also have to answer certain questions, printed on the form, as to his own health, occupation, and habits, and the health of his parents, brothers, and sisters, and he must answer these questions truly to the best of his knowledge.

4. He must also, if possible, obtain a certificate of his birth, either from the Registrar of the district in which he was born, or, if it suits him better, from the Registrar-General of births, deaths, and marriages, at Somerset House, Strand, London. The certificate may be obtained by personal application between the hours of ten and four, or by letter to the Registrar-General. The letter must state that the certificate is required for insurance purposes, must give as nearly as possible the place and date of birth, and the Christian names and surnames of the parents. In the letter must be enclosed postage stamps to the value of 3s. 7d., that being the fee payable by law for the certificate. If the person desiring his life to be insured happens to have been born before the 30th June, 1837, or not to have been born in England or Wales, he will not be able to obtain a certificate of birth from a district Registrar or from the Registrar-General, and he must then endeavour to obtain a record of his birth or baptism from the minister of the church or chapel at which he was baptised. If he cannot do this, he must state on the form what other means he has of proving that he was born at the time stated by him. If any respectable person who has known him from his birth will declare before a magistrate that he was born at the time stated by him, such declaration will be accepted as proof of the birth having taken place at the time stated.

5. He must also state on the form the names and addresses of two householders, and the names and addresses of two persons under whom he has worked or served, and who can give the necessary information as to his age, health, and habits.

6. When he has filled up the proposal form in the manner described, he must take it, together with the certificate of birth or baptism, to one of

* Concluded from page 371.

the post-offices which have been opened for insurance business, and there sign the declaration which is printed at the foot of the form in the presence of the postmaster.

7. The proposal form and certificate of birth or baptism will be forwarded to the Postmaster-General in London, who may direct the person who desires his life to be insured to present himself to a medical man for examination; and the Postmaster-General will endeavour to select for this purpose a medical man living near to the person desiring his life to be insured, and who will make the examination at a time convenient to that person.

8. If the proposal is accepted, there is no further trouble than is involved in the payment of the stipulated premiums at the proper periods at the most convenient Money Order Office, the receipts for the premiums being kept in a little book similar to the ordinary Savings Bank deposit books.

These are the essentials of the transaction, and the person proposing to insure is put to no charge for medical examination, or for anything whatever beyond the cost of the certificate of birth, or other evidence of age.

The Post-office authorities have sought by every possible means to carry out the beneficent designs of Mr. Gladstone, and it remains for the working men of England to show that they can understand and appreciate a measure which more than any other legislation of our times is capable of helping the really industrious and prudent man by showing how best he can help himself.

Of the principle of life insurance, M. Edmond About, the distinguished French writer, has thus recently written: "Either the soul is immortal, or that light which shines within us is extinguished by death. On the first hypothesis, the assured will enjoy, at least in prospect, the blessing which he will leave behind him. On the second, he will console himself in thinking that he shall not die altogether: his good work will survive and prolong for some time his useful existence."

THE MINIATURE OF THE QUEEN FOR MR. PEABODY.

THE word "miniature" scarcely represents what the importance as regards the size of the likeness will be, for, though only half length, the painting is 14 inches long by 10 inches wide. For the first time for the presentation of her portrait to a private individual, Her Majesty sat in the only robes of state she has worn since the death of the Prince Consort, the costume in which she was attired at the opening of the present Parliament. This was a black silk dress, trimmed with ermine, and a long black velvet train, similarly adorned. Over her Mary Stuart cap is the demi-crown, while the Koh-i-noor and one rich-jewelled cross, presented by Prince Albert, form her only ornaments. To complete this portrait, Her Majesty gave Mr. Tilt several long sittings, and has now expressed her unqualified approval of the water-colour shown at Mr. Dickinson's. This, however, is but the commencement of the process. The portrait is to be done in enamel by Mr. Tilt, on a panel of pure gold. In these enamel paintings, to bring out all the brilliancy of their colours, they have to be burnt in a furnace at least five, and generally six times. The heat to which they are subjected is so intense as to be only short of that which would fuse gold, and the most exquisite care is necessary neither to let the picture heat too soon, nor, above all, cool too rapidly, as in either case the enamel would crack. So large an enamel portrait has never been attempted in this country. It has, therefore, been found necessary to build a small heating furnace specially for the execution of this work. It will take about six weeks to complete all the processes, when the picture will be mounted in a most elaborate and massive chased frame of pure gold, surmounted with the royal crown enamelled on the same metal in colours. Altogether it will form a gift worthy both of Her Majesty and of the gentleman to whom she presents it. In fidelity of portraiture the likeness is not to be surpassed, and, of course, it was not till after many and long sittings that such perfect success was accomplished. After being submitted to the Queen on its completion, it will be forwarded to Mr. Peabody, who intends to deposit it where it may be best seen in a large institution which he has founded in Boston, his native town.

SOUTH LONDON DISTRICT OF ODD FELLOWS.—From the annual statement of this association for 1865, it appears that the amount of the capital of the Manchester Unity, to which it belongs, was, on the 1st of January, 1866, £56,680. Of the capital, £45,667 formed the sick and funeral fund. The number of members belonging to the Unity was 368,847, besides 19,143 in the colonies. There had been an increase of 14,481 members during the year 1865.

THE MACHINE *v.* THE WHEELBARROW.

A NEW machine, which is attracting much attention, is at work on the Seine. The boats which bring up the broken pebbles for macadamising, or for laying the foundations of buildings, are just now moored off the Prefecture de Police as being the nearest point to the new Hotel Dieu, at present in course of construction. Between the shore and the nearest boat is moored a little flat-decked craft, on which is fixed a steam-engine turning on a pivot, armed with a long iron bar, placed at the angle of 45 degrees. By means of a chain, which is wound by steam over a wheel, an iron bin, which contains a cubic mètre of the broken pebbles, is lifted from on board the vessel, carried off, and deposited on the quay in less time than it would take to describe the manœuvre. Another dangerous and degrading toil is thus dispensed with, and the wheelbarrow traversing the narrow plank, with its heavy burden and tottering conductor, will be seen no more.

BELGIAN METHOD OF TEACHING DRAWING.

LAST autumn, M. Hendrickx, inspector of the drawing classes in the communal schools of Brussels, was authorised by the Minister of Public Instruction to make an experiment in the Lycée Bonaparte, in Paris, of a system which is reported to have yielded excellent results in Belgium. Fifty adults answered the invitation; they consisted of students of the Polytechnic and Philetechnic Associations, commercial clerks, fitters and mechanics, in the employ of the Orleans Railway Company, and other workmen. With one single exception, the whole of these adult pupils were totally ignorant of drawing. After twenty-two lessons of one hour's duration each, with some unaided practice at home, the pupils were able to execute complicated designs with a firm hand and considerable taste. At the urgent request of the class, the Minister has decided that the experiment shall be continued, at the cost of the State, in the Lycée Charlemagne, by M. Bourson, painter, and associate of M. Hendrickx. The same gentleman has been appointed to conduct a similar course for the pupils of the primary normal school of Versailles, and another especially adapted for the teachers of the Seine-et-Oise. The system is also now under trial at Lyons.

The course established at the Lycée Bonaparte was mentioned in the *Journal* at the time; and it will be interesting, and perhaps useful, to reproduce a *resumé* of the report made on this method of teaching, which M. Armand Dumaresq, a well-known historical painter, and president of one of the classes for the Exhibition of 1867, has made officially to the Minister of Public Instruction in France.

M. Dumaresq says that the method of M. Hendrickx is a compilation from ancient systems. The bases of the science of drawing were laid down by Leonardo da Vinci and by Albert Durer, who published a treatise on drawing in 1557. All modern authors, says the reporter, from Paillot de Montabert downwards, have borrowed from Albert Durer. The work of the last-named artist comprises the geometric system of including within a square or a cube the figure that is to be demonstrated. M. Hendrickx quotes this idea, and makes it the foundation of his whole system. This method of framing in a known figure the design to be drawn is good, as it enables the pupil to pass readily from the known to the unknown; he finds in the horizontal and perpendicular lines of the diagram a series of starting-points, which serve the same purpose as those used by sculptors for the roughing out of a block of marble.

Albert Durer advocated the principle of designing by compass and rule as the Greeks did; Michael Angelo was the first to set up the dictum that an artist's compass should be his eye, and from that time the painters, Raphael amongst the first, abandoned the method of the Greeks, and a revolution came over art.

M. Hendrickx, in taking up this forgotten method, has, then, not invented a new system, but only made a discovery in the past. A good idea of his mode of carrying out this system will be obtained from a description of four books of the first and second degree. The first two contain the demonstration of lines and surfaces, and their application to forms represented geometrically such as cubes, figures derived from the cube, and invariably enclosed in a cube, sections, cylinders, cones, pyramids, circles, and spheres, and, lastly, curves of the teeth of wheels, balusters, and vases, the series being carefully graduated. The other two books contain the construction of the principal generic figures:—First, a portion of forms of the first degree, with their shadows; then the elements of the proportions of the Tuscan order; of the leaves of living plants, such as the vine, oak, laurel, narcissus, and acanthus, and their analysis in an ornamental point of view; lastly, the proportions of the human head and body. These models are well designed and well chosen, and their decorative quality is made clearly apparent to the student. The third series of books, or copies, contains the complement of the two former, and prepares the pupil for the study of the round.

Whatever may be the merit due to M. Hendrickx for having adopted the method of the Greeks as taught by Albert Durer, his practice in teaching deserves the greatest attention—the principal point consisting in the fact that the students draw with chalk upon the black board from the model produced before their eyes, in the same manner, by the teacher, who, at the same time, explains to them the method by which he produces what he places before them for reproduction. The pupils copy the drawing upon whatever scale they please, and the teacher points out any errors into which they may have fallen. Between one lesson and another the students are expected to reproduce on paper what they have previously drawn on the board, choosing, as before, whatever scale or size they please, but, of course, preserving the proportions. The result of this reproduction from memory gives the exact measure of the appreciation of the lesson.

Scientific and Useful.

A METAL THAT EXPANDS IN COOLING.—Lead, 9; antimony, 2; bismuth, 1 part. This metal is very useful in filling small defects in iron castings, &c.

DUCTILITY OF GLASS.—A tube of glass may be drawn, by careful manipulation, with an external diameter of only $\frac{1}{1000}$ of an inch, yet still retaining the character of a tube, with its internal orifice and an external and internal surface.

ALTHOUGH every possible care has been taken in the construction of Greenwich Observatory to obviate vibration, the delicacy of the instruments is such that the sudden shutting of the outer gate is said to be sufficient to cause a star to start out of the field of the equatorial telescope.

INCOMBUSTIBLE STRAW.—It has been proved, by repeated experiments, that straw, saturated with a solution of lime, or common whitewash, is incombustible. This fact is of great importance, especially as thatch is not only rendered fireproof, but more durable. A solution of alum has been tried, but being soluble, the rain destroys its virtues.

ALUMINIUM ARMOUR.—A trial has just been made at Florence of a cuirass in aluminium, which is as light as an ordinary waistcoat, nearly as flexible, and capable of turning a musket-ball fired at the distance of thirty-eight paces, and of resisting a bayonet thrust from the heaviest hand. Each cuirass costs only 25 francs. Two regiments are, it is said, to be immediately provided with them.

THE METALLIC SAND OF NEW ZEALAND.—Travellers along the sea-shore of New Zealand have to wear veils to protect their faces and eyes from a fine metallic sand which rises with every puff of wind. This sand proves, upon analysis, to be the purest ore of iron known. Its composition is:—Peroxide of iron, 88·45; oxide of titanium with silica, 11·43; loss, 12. Experiment shows that the ore yields in the furnace 75 per cent. of the best iron; or by cementation an excellent quality of steel. The smelting was done in a little furnace, with a hearth seventeen inches diameter and ten inches deep. A ton of fuel (coke) made a ton of metal titaniferous, which, added in the proportion of five per cent. to ordinary steel, transformed it to first quality.

IMPROVEMENTS IN GUN-COTTON.—Gun-cotton is now made into ropes for storage, and kept under water. When an order is received at the manufactory, a few hours suffice to send the cotton on its way. It has been found that by making the ropes with many air channels through the mass the cotton explodes almost instantaneously, and is as violent in action as the strongest fulminates. Charges for guns are now made in two parts—an exterior composed of cotton of loose texture, the ignition of which starts the ball, and an interior of denser material, which supplies the gas necessary to keep up the constantly accelerating speed of the ball. The result is a great gain in initial velocity. Compared with gunpowder in an Enfield rifle, the cotton gave a trajectory having an incurvation of $2\frac{3}{8}$ inches and the powder $3\frac{3}{8}$ inches in the first 100 yards.

NEW SUBSTITUTE FOR GUNPOWDER.—Among the substitutes for gunpowder that have been proposed, the most recent is *gun-paper*, which is said to be superior to either gunpowder, gun-cotton, or gun-sawdust, in economy, efficiency, and safety. Time, however, must test the validity of these extraordinary claims to public favour; but, so far as experiments have yet been made on the subject, the results appear very satisfactory. Gun-paper is formed by impregnating paper with a composition consisting of about 9 per cent. chlorate of potash, $4\frac{1}{2}$ nitrate of potash, $3\frac{1}{4}$ ferrocyanide of potassium, $3\frac{1}{4}$ powdered charcoal, 0·05 starch, 0·06 chromate of potash, and 79·9 water, the liquid having been boiled for an hour. This mixture is perfectly safe; and the dry paper is exploded only by fire, or an equivalent temperature, but not by percussion. The sheets of prepared paper, while wet, are made into rolls of any required size, and are dried at a temperature of 212° Fahr.; they then present the appearance of a compact greyish mass, and may be cut into cartridges of suitable length. These are said to be more powerful, and to cause less smoke and fouling than those of ordinary powder; and may be protected from damp by coating them with a solution, in acetic acid, of xyloidine, obtained by acting on paper with nitric acid.—*Scientific Review.*

"CANNELITE."

Cannelite has been found in New Brunswick in beds of from two to thirteen feet in thickness, and the best quality when distilled yields 50 gallons of crude oil to the ton of 2,240 pounds. The volatile products are obtained with great facility; the mineral does not swell in the retort, and is completely exhausted within eight hours. Some varieties leave a coke behind, like vesicular lava, others a bulky ash, nearly of the same form as the original material, but containing (according to the analysis of Dr. Hayes) 16 per cent. of fixed carbon. There have been imported into Salem, Mass., 3,000 tons of this mineral, which yielded 50 gallons to the ton. The further importation into the States is stopped by the abrogation of the reciprocity treaty with the British provinces. The available deposits at present known are estimated to exceed 20,000,000 tons, capable of producing 1,000,000,000 gallons of crude oil, of the specific gravity of 29° Beaume, and this can be shipped free on board at 12½ cents per gallon. The same mineral has been discovered in Nevada; and a similar substance, "canuel," is being worked in Wales. These discoveries compel us to think of the treasures slightly veiled from our view, which increased scientific knowledge is gradually discovering on our eastern seaboard—metals of all kinds, building stone of rare beauty, coal, oils, and other substances, waiting for industry and capital to render them serviceable—treasures not so dazzling as the piles of precious metals from our Pacific States, but equally valuable to a practical people. The mineral wealth of the great American continent seems altogether inexhaustible.

THE ATLANTIC TELEGRAPH.

The new Atlantic cable is now completed, and it has been arranged that the *Great Eastern*, with this and the remains of the old line on board, shall sail from Sheerness on Saturday, the 30th instant. Stopping for a time to coal at Beerhaven, she will reach Valentia about the second week of July, and the shore end of the cable having been connected with the main line, the operation of laying will be commenced. The big ship will first lay the new cable from the Irish coast to Trinity Bay, Newfoundland; and, assuming this to be successfully done, and telegraphic communication established, she will then steam back to the middle of the Atlantic, and attempt to pick up the cable lost overboard in July last. The 1,200 miles of cable now lying on the bed of the Atlantic are to be connected with the 1,100 miles left on board; and, if all goes well, the ship is to retrace her course to Trinity Bay, and so complete a double line of union between the two continents. The new cable differs from the old in only two particulars. The conductor, it will be remembered, is composed of seven copper wires—six round one—each wire separately imbedded in Chatterton's compound, and the whole surrounded by layers of gutta percha, so as to form a "core" half an inch thick; this, again, is further protected by ten solid iron wires, each covered with five strands of Manilla yarn, the wires being laid spirally round the core. In the old cable the yarn was tarred; in the new it is left white, to decrease weight and facilitate the discovery of foreign substances, and the iron wires have been galvanised. This year 2,730 miles of cable will be shipped, to complete both lines, the length put on board last year being 2,300 miles.

Iron Smelting.—At a recent meeting of the London Association of Foremen Engineers, Mr. J. M. Aubridge (of Messrs. Simpson's, Pimlico) read a paper on "The Various Modes of Smelting Iron, and their Results." He proceeded to trace the history of iron smelting from the very earliest periods of recorded time, and, by means of diagrams, which he drew *en courant*, illustrated clearly the gradual progress of improvement down to our own day. As a practical ironfounder, the reader recounted much of his own experience, and said that the great secret of economical and effective smelting consisted in obtaining for the purpose a rapid current of common air, so as to produce complete combustion of the fuel employed; and the speedy creation of a large quantity of carbonic oxide gas was the consequence of such an arrangement. The blast-pipes should in all cases fit the tuyere holes closely, so as to prevent the waste of air and to direct the full force of the current into the furnace. It was desirable also to adopt what was known as the "drop bottom" in furnaces, so much used in America, and, he was sorry to say, as yet so seldom adopted in this country. It was desirable to lessen, as far as possible, the expenditure of manual labour, and this last arrangement was essentially a step in that direction. After a man had been engaged in working a furnace for several hours, it was rather hard to give him the task of raking it out and quenching it. By means of the drop bottom this might be accomplished in a few minutes, whereas it was a laborious and tedious process in the other case, and much more costly.

Bornemau says that the softest Bessemer steel is at least as strong as the best Swedish chain iron, and its strength increases with the per-centage of carbon to one per cent., when it is equal to about double the strength of the best chain iron.

Facts about Ventilation.

Since men must breathe, it is as well to understand the conditions under which it can best be done, so far as the supply of the material is concerned. According to Dr. Percy's admirable and lucid report on the ventilation of the House of Commons, to which we have already referred, air itself is somewhat an imaginary article. The modes in which we suppose that we can best attain it are perfectly illusory. For instance, in summer we open our windows with a view to let in fresh air, and this mode of obtaining air is so associated with our most natural and common experience, that few persons are prepared to learn that more air can be obtained with the windows shut than when open. This Dr. Percy, in his admirable report on the ventilation of the House of Commons, assures us has been clearly and repeatedly established by experiment.

When the windows of the Houses of Parliament are opened, the quantity of air which ascends into the House is much diminished, and the temperature generally rises several degrees a few minutes afterwards. That a room should grow warmer when cold air is admitted into it is certainly a violation of what any one would ordinarily expect. Those, however, who read of this recently established fact, should use precautions when acting upon it. They must not overlook that Dr. Percy's position is, that a better system of ventilation can be devised and put in operation than mere ventilation by the open window. But if there be no ventilation at all in the house, the windows had better be opened, as that mode of ventilation is far better than none.

The complaint made by members of Parliament as to the temperature of the House, are often of a very curious and contradictory character. A member who has long been fasting will complain that the air is cold; one who has just dined and taken wine will complain that it is too hot. An aged member wishes the place warmer; a younger member would like it colder. One accustomed to cold baths is comfortable in a low temperature; one who does not use cold ablutions is uncomfortable under the same conditions. A soldier who has just come home from the East finds the House chilly; another gallant officer who has just returned from a command in the north, finds it oppressive. A member feeling unwell wishes Dr. Percy would let in more hot air, and when he becomes better he applies for colder air. It has occurred that complaints have simultaneously proceeded from two members sitting either side by side or close to each other, one complaining that the temperature was uncomfortably low, and the other that it was uncomfortably high. It should ever be borne in mind, observes Dr. Percy, that our individual sensations may be treacherous in the indication of temperature, as we are not accurate, invariable, and unimaginative instruments like thermometers; and that a temperature which may be agreeable to ourselves, may not be equally so to our neighbours.

In the discussion upon Ventilation which occurred at the Social Science Congress at Edinburgh, three or four years ago, Mr. Rawlinson stated that, when Windsor Castle was sought to be improved in the matter of ventilation, after the death of Prince Albert, the most perfect plan that could be devised, consisted of the very simple process of making the windows open at the top, and keeping a fire at the same time in the room. In the absence of scientific modes—such as are adopted in the House of Commons—we believe this is the most effectual method suitable to all habitations. It was also stated, on high medical authority—if we remember rightly, that of Dr. Christison—that, in cases of contagious fever, no healthy person would become infected if that plan of ventilation was adopted. It would be necessary that only one patient should be in a room. The attendant would not, under such circumstances, be liable to catch fever.

Various systems of ventilation have, from time to time, been adopted in the House of Commons, and the most costly have proved the most futile. Sir Goldsworthy Gurney was the advocate of the steam jet plan, for some time applied to the ventilation of collieries. The waste steam rushed up a funnel, dragging after it gaseous products, and creating an active current. Another was the plan of mechanical propulsion by fans. That has long since been abandoned, and the greatest authorities on ventilation have at last agreed that the plan adopted in collieries at the present time is, after all, the best. The air in the House of Commons is now exclusively put in motion by means of heat, precisely on the same principle as in most of our collieries. When air is heated it expands, and, as it does not thereby increase in weight, it becomes specifically lighter; ascending through cold air for the same reason that a balloon, filled with coal-gas, rises in the atmosphere, or oil in water. Heat is applied by coke fires of the simplest construction. There are two great up-cast shafts—namely, one of the turrets of the Victoria Tower and the Clock Tower. There are, also, the following additional up-cast shafts—namely, the Peers' shaft, the Commons' shaft, the Speaker's shaft, the river-front shaft, the north end shaft, the west front shaft, and the Black Rod shaft. In the first two shafts there are coke fires for the sole purpose of causing an upward current of air.

One of the highest scientific and practical living authorities on the subject of ventilation, General Morin, has also decided in favour of this system. When properly carried out, and carefully attended to, it is all that can be desired, both in regard to simplicity and efficiency. It requires no machinery, and is not liable to any sensible derangement, except during sudden gusts in tempestuous weather, and the only labour which it needs is that of a common stoker. Such is the statement and very words of Dr. Percy, and seldom has a more interesting and instructive report been presented to the country than his.

Self-acting Railway Signals.—Sir Cusack P. Roney describes a new signal which he has seen in Paris. It is the invention of Signor Vincenzi, an Italian engineer, and works by electric agency. It is difficult to describe, but the mechanism comprises cast-iron cases placed along a railway, and containing electric apparatus, which causes the whistle of the locomotive to sound when the way is not clear, or when a train in advance has just passed. The communication between the apparatus and the engine is made by means of steel arms, which meet and act together. The inventor is said to be willing to test his apparatus at his own cost on an English railway.

A New Explosive.—A few days ago, the master of the ship *St. Joseph*, recently arrived at Boston, U.S., having found a suspicious box on board his vessel, marked "sodium," flung it overboard. As soon as the package touched the water an explosion occurred, lifting the sea in an immense column to the stern of the vessel. We infer from a San Francisco journal that it was a new chemical mixture called sodium-amalgam. This material is never manufactured in very large quantities, though it has been advertised for sale in San Francisco, one firm claiming to have as much as 200 oz. for sale. The amount does not seem large, but when it is understood that the explosive power of 1 oz. of sodium is equal to that of about 25 lb. of gunpowder, or 2½ lb. of nitro-glycerine, it can readily be conceived that even 15 oz. or 20 oz., exploded in one place, would create immense havoc. And when one further reflects that even so little a thing as a spoonful of water coming in contact with 200 oz. of sodium would occasion an explosion equal to that which would be occasioned by the ignition of 5,000 lb. of powder, or the concussion of 500 lb. of nitro-glycerine, we can form some conception of its tremendous destructive power.

Pinholes in Photographic Negatives.—This defect in negatives, which is not only very annoying, but of frequent recurrence, has for some time been known to arise, with old silver baths, from the formation of crystals of iodide of silver, which adhere to the collodion film while in the bath, and during development, and in the end leave a small hole, that becomes more distinct when the print is strengthened. These crystals make their appearance most usually in warm weather, since the iodide is less soluble in heat than in cold. But pinholes exist which cannot be traced to this cause; and they have been shown by Dr. H. Vogel to arise from the presence of crystals containing sulphate of silver, due to the use of impure iodisers, impure nitric acid in dissolving the silver, &c. The presence of the sulphuric acid may be ascertained by adding to a portion of the silver bath which is to be tested, after acidifying it with a few drops of nitric acid, a solution of nitrate of baryta, which will produce turbidity, after a while, if sulphuric acid is present. The test will be more satisfactory if the silver is first precipitated with pure hydrochloric acid. The addition of nitrate of baryta to a silver bath for the purpose of throwing down the sulphate, if done with caution, not only produces no injurious effect, but greatly augments the intensity of the negatives afterwards obtained with it, so that they require no strengthening. A certain amount of hardness is imparted; but the addition of a little of a new silver bath will, if desired, prevent this augmentation of intensity. If, however, the nitrate is used in excess, it will itself produce pinholes, as it is a salt of difficult solution in water, and is precipitable in crystals by alcohol.—*Scientific Review.*

Things Talked About.

The Reform Bill is certainly shelved. Payers of a £7 rental in boroughs must wait awhile before they are able to present themselves at the hustings. The amendment carried against the Government would have had the effect, by substituting a £7 rental for a £7 rental, of virtually raising the franchise qualification to about £9, and so excluding many thousands from the privilege of voting. The lodger franchise had not come on for discussion in committee; but, of course, that most important provision shares the fate of the Bill generally. As we said elsewhere, working men who do not live in boroughs in houses rated at £10 must wait for "the good time coming."

But, in fact, questions of home politics are just now overshadowed by the terrible outbreak of a Continental war. Now that the spark has been kindled, whither the fire will reach no man can predict; but we may feel a sad certainty that manufactures, trade, all that makes the working man in every country happy and prosperous, will experience fearful depression. Before a blow was struck, the pressure was beginning to be felt. The Berlin Town Council, we read, is endeavouring to raise a loan of three millions, at a high interest, for the purpose of undertaking public works, which will give employment to starving operatives. Already the very threat of war is reproducing in the Prussian capital the situation of Lancashire during the cotton famine!

The House of Lords has sanctioned the clause in the Metropolitan Railway (Additional Powers) Bill, which relieves the company of the liability to make full compensation to persons who may lose their lives or be injured while travelling in ordinary trains at what are known as workmen's fares. Men who ride in "workmen's trains" are, perhaps, not aware that, by special enactments, the principle of compensation otherwise generally acted on does not apply to them. In no case need the company, however great the negligence of the officials, pay more than £100 to a person injured, or the family of a person killed, if travelling by those trains. Believing, as we do, that these low fares are amply remunerative to the company, we concur in the opinion of Lord Stanley of Alderley, "that railway companies should be liable to the full extent, as estimated by a jury, for injury done to passengers through the negligence of the railway servants. He knew of no sufficient reason to induce the Legislature to order that the family of an artisan should not be compensated to the full extent of their loss in case he should be killed by an accident in a railway train which had arisen, in the opinion of a jury, in consequence of the negligence of the railway company's servants."

A dividend at the rate of 11s. 4d. in the pound has been paid to the depositors in the Birmingham Penny Bank, which recently failed. The number of depositors was 3,228, and the amount of the dividend, larger than was anticipated, is due to a public subscription. The authorities of the Post Office Savings Banks sent down a large number of handbills to be distributed among the depositors, explaining in a very brief manner the objects and mechanism of the Post Office Savings Banks. It was also arranged that, during the three days appointed for paying the dividends to the depositors in the Penny Bank, the Head Post Office Savings Bank in Birmingham should be kept open until half-past eight p.m., to afford to such depositors as might wish to do so an opportunity of placing their money where they can obtain direct Government security for its repayment.

We have before us the rules and regulations of the Kent Agricultural Labourers' Protection Society, which has been in existence a little more than a month. The contribution of members is 1s. a month, and 1s. entrance fee. The head-quarters of the society are at Maidstone. The objects aimed at are—an advance of 6d. a day on the present rate of wages; 2d. in the shilling on the present scale of piecework; 4d. per hour for every hour over ten hours and a half's labour per day; and a cessation of work after four o'clock on Saturday afternoon. As the first attempt at organisation by agricultural labourers, the society claims attention and sympathy.

There has been an exhibition at the Society of Arts, Adelphi, of a collection of competitive plans for labourers' cottages (detached). Prizes of £10 and £5 were offered by the Central Cottage Improvement Society; and no fewer than 107 architects competed. Something in the way of improved dwellings ought to result.

At length, the long dispute at Sheffield has terminated, and the men have gone to work on the old terms; but the employers have promised to consider the claims of any particular section of the operatives who may appear to them to have good grounds for claiming an advance. At present, then, the sixteen weeks' struggle has resulted in the discomfiture of the men, who, it is stated, have lost nearly £80,000 in wages alone, incurred a vast amount of debt, and have the mortification of seeing erected the machinery against which they protested. It is a sad history, and should be taken to heart.

The Scotch ironmasters at Coatbridge have announced their intention to reduce wages, and it is believed that a lock-out, in case of opposition from the men, is decided on. In this case, the strike certainly seems to be on the master's side.

The dispute between the operatives and their employers at Barnsley has terminated in a compromise.

The female power-loom operatives of Heckmondwike, Dewsbury, and Mirfield, have struck for an advance, following the example of the blanket weavers. The very novel feature of a conference between female delegates and their employers was presented. The reporter, who can scarcely avoid a joke at the expense of proverbial female talkativeness, says:—"The women, of course, had plenty to say, the debate lasting over two hours. The origin of the strike, and the manner in which it had been conducted, were freely commented upon by the gentlemen, but the women expressed their determination to stand out for the advance. The appeal to reason was followed by a little coaxing, which had the effect of inducing the female delegates to agree to go on at an advance a halfpenny per wartern for two months, providing the manufacturers would agree to give another halfpenny at the expiration of that period."

A fishing association is about to be established at Dartmouth, in Devonshire. The capital is £10,000 in £5 shares.

The miners of some of the largest collieries in South Wales have threatened a strike for an advance of wages, and notice to that effect has been served upon the employers, who immediately convened a meeting, at which it was determined to resist the demand, and to establish a permanent masters' association. The first resolve of the new association is to the effect that, so far from conceding an advance of wages, the time has arrived when a reduction became necessary, and it has been ordered that this decision be communicated to the men. So that, we fear, a protracted and disastrous contest is imminent.

The seamen on the Tyne have resolved to strike, unless an advance of wages is conceded. They ask for £5 per month for the Baltic, Quebec, and British colonies in America; for the Mediterranean, £4; and for the southern trade beyond the equator £3 10s. per month.

It is stated that the Board of Treasury contemplate a measure regarding clerks in public offices, which, though doubtless intended to have a wholesome effect, may, if carried out, be productive of considerable annoyance, if not hardship. All clerks in Government offices are to be prohibited from connecting themselves in any way with public companies. The object, of course, is to keep the clerks aloof from extravagant and imprudent speculations; but it may have the effect of interfering with such provident and admirable associations as the Civil Service Co-operative Supply Association, the shares in which are nearly all held by persons in the employ of Government.

The members of the Clyde Shipbuilders and Engineers' Association have decided on opening their works to such non-society men as are willing to work on the terms offered. They are to work fifty-seven hours a week, and be paid fortnightly. The members of the association declined to have a conference with the delegates or members of Trade Unions, a step which does not promise to smooth the way for a settlement of the dispute.

Water-Meter.—A premium has been offered by the Industrial Society of Amiens, in the following terms:—"The proprietors of steam-engines are in want of a water-meter which will indicate exactly the quantity of water injected into the boiler, whatever be the pressure. This apparatus must be one easily set up, not subject to get out of order, and capable of registering the quantity of water to within two per cent. of the actual volume. It is not a memoir that the society wishes for, but an apparatus in working order, on which experiments can be made; and if a water-meter be presented appearing to be of practical utility, the society will use every effort in its power to promulgate the use of the contrivance. The meters to be experimented on should be sent to the office of the society before March 1, 1867."

New Hygrometer.—A new hygrometer has been recently invented, and presented to the Academy of Sciences, by M. Monier. It is in the form of an aneroid barometer, about 4 in. in diameter, and 1 in. in thickness, the rim being pierced to give admission to the air. As in the hygrometer of Saussure and others, the sensible organ of the instrument is a hair, but by a peculiar arrangement M. Monier is able to employ a hair 14 in. long, which gives his instrument great sensibility. The graduation of the index face is effected in the following manner:—The instrument is placed under a bell-glass upon unslacked lime, and the point at which the needle rests is marked zero; the lime is then replaced by a sponge dipped in water, and the new position of the needle marked as 100°. The index is then subdivided into 100 equal parts. A small thermometer is fixed on the face of the instrument. The new hygrometer is perfectly portable; the hair is stretched by a watch spring of which the tension is only equal to three-tenths of a gramme. The inventor says that to obtain an idea of the delicacy of the new instrument, it is only necessary to place it in a room in which the gas has just been lighted, and immediately the steam arising from the combustion will act upon the hair and cause a deflection of the needle; or place the hand around the case of the hygrometer, and the needle will immediately advance several degrees.

Co-operative Intelligence.

Saltley.—The workpeople of the Britannia Carriage Works, Saltley, have established an association, called the "Britannia Co-operative Meat Society," for the purpose of supplying themselves with the very necessary article, meat. The society has been in operation only a few weeks, and has been attended with very gratifying results, as the following statement of the quantity of meat sold on Saturday week last will testify—viz., one ox, one calf, nine sheep, and one lamb. The highest price charged for the best joints has been 9d. per lb., and the quality has been of such a character as would defy competition with any joint sold at the butchers' shops at a much higher price.

General Information.

CLUBS AND INSTITUTES.

Newcastle Working Men's Club.—From the recently published report of this useful institution we learn that the number of members during the quarter has been three honorary, one yearly, 22 half-yearly, 100 quarterly, 87 monthly, and 223 average weekly (the large number of 2,897 weekly tickets having been sold), giving a total weekly average of 378 members, which, being compared with the similar quarter of last year, shows an increase of 26 members per week. What is peculiarly gratifying, too, in connection with this increase in the number of members is, that it consists of the best and most intelligent class of workmen, the holders of half-yearly, quarterly, and monthly tickets. The news-room of the club, which is large, convenient, and well lighted, is well supplied with daily and weekly newspapers, and the best and most popular magazines. The classes during the quarter have been tolerably prosperous. It is in contemplation shortly to hold a chess tournament. The Monday evening entertainments during the quarter have been very successful. The weekly receipts from the entertainments this quarter are nearly fifty per cent more than during the similar quarter of last year, whilst the expenses of management have been considerably reduced. The income for the quarter (inclusive of a balance of 12s. 10½d. from the previous quarter) has been £61 15s. 10d., and the expenditure £53 6s. 0½d., leaving a balance in favour of the club of £8 9s. 9½d. The committee, during their brief period of office, have made strenuous efforts to sweep off the existing liabilities of the club, which at the commencement of the quarter in March amounted to £38; in this they have partly succeeded, and when the increase in the number of members is taken into consideration, they may reasonably hope shortly to have the pleasure of announcing the Working Men's Club to be entirely free from debt.

EMIGRATION.

News of the Emigrants in Queensland. The Dark Side of the Picture.—A late resident of Over Darwen, Lancashire, writing from Queensland to his relatives, says:—"The fever is raging very badly here at present through the drought, for there has only been one shower of rain since Christmas. It would make you grumble if you were to pay 5s. for a small cask of dirty water, which we are doing at present, while you can sit and watch the running brooks of clear water, and listen to the little pebbles that run at the bottom, and the thrush and blackbird pouring out their sweet songs; but that is not so here, for we have no song birds—only a chirp and off they go, though there is plenty of beautiful birds. I am going to tell you the true state of things in Queensland at the present time. There is Mr. J——, of L——, and Mr. K——, of B——, sending out as many poor folks as they possibly can; but, mark you, they do not send out many men who have got capital. I should like to ask Mr. K—— or Mr. J—— how all the poor emigrants have to live when they arrive here, for there are thousands of honest, sober, and harkworking men walking the streets of Brisbane, and cannot get a job of any sort of work; and when you do get work, you do not know whether you will get paid for it when you have finished. I know men who have bought both houses and land, that would gladly sell all they have—yea, even for less money, that they might but put their foot once more on English soil. They tell the men at home that they can get plenty of work and good wages in Queensland. Perhaps they might do so when Mr. K—— was out here; but let him come now, and he will find a great contrast between those days and now, for there are as good men as ever he was (and in the same business) that would gladly take a day's work with the pick or shovel if they could get it. If a man is getting £1 a week at home, he is far better off than a man who is getting £2 a week out here. I went down to town last week, and was there when the ship *Light of the Age* arrived, from Scotland, with about 400 poor emigrants upon it. The day after (being Good Friday, we had a holiday) I and my mate went down to the depôt: it was ten o'clock in the forenoon when we arrived there, and I there saw a poor woman with a little child in her arms, eating a hard ship biscuit, and not a drop of water or anything to drink to it. The rest had not broken fast at that time. I think it high

time that a stop should be put to such like carryings on."

Another View of Queensland Emigration.—A shepherd, who emigrated from Scotland to Queensland last autumn, in a private letter just received by his friends near Edinburgh, gives the following account of his experiences in the new colony:—"We landed in Rockhampton on the 26th September. We were all taken to the Government depôt and supplied with food, or rations as it is called here, daily. The day after we landed, the agents in the town came and engaged nearly all the single men and women to different masters, and different parts of the country. The single men were all engaged as shepherds—and very few shepherds amongst them. The married couples with no children met with a ready demand at wages from £60 to £70 a year, with their rations—rations for one man or woman per week is 14 lb. of beef or mutton, 8 lb. of flour, 2 lb. of sugar, and ¼ lb. of tea. Single men's wages were from £45 to £50 a year; but being strangers, and not knowing the real wage, they were rather taken advantage of. The wages here for a labouring man is 8s. per ten-hour day, and for shepherds £60 per year. A single shepherd lives in a hut by himself, and cooks his own victuals. I was 120 miles up the country, and saw a good many shepherds at their work. I walked up and down, and stayed in some of their huts all night, where I learned that any person went a sheep-herding in this country, and that the most a shepherd had to do was to put his sheep in the yard all night, let them out in the morning, drive them out to feed, keeping them always in a drove, and return to the yard with them at night. He neither assists at clipping nor lambing. Those who clip get 4s. per score with rations, and those who lamb, 25s. per week with rations. In fact, a man may be a shepherd all his life here and know nothing about sheep after all. Queensland is not what it was represented at home. There are no crops grown here—not so much as a garden at either hut or house. The land is totally covered with trees. The country is so dry and warm that the watering of the garden would cost more than the crops would produce. They count upon nine months of dry weather and three months of constant rain; and I think, by the appearance of the land, that at the end of the three months fully the half of it must be covered with water. It is, no doubt, of deep rich soil; but owing to the want of a regular supply of rain, I do not think it will ever grow crops; while, if there was a regular supply of rain, I think it would grow almost anything. It is spring here just now, and far hotter than summer is in Scotland. Provisions are pretty high here in Rockhampton. They are much as follows:—The 4 lb. loaf, 1s. 4d.; flour, 4d. per lb.; oatmeal, 6d. per lb.; cheese, 1s. 2d. per lb.; butter, 1s. 6d. to 2s.; eggs, 1s. 6d. to 2s. per dozen; beef, 2d. per lb., without bones; mutton, 2d. per lb. No lambs are killed here, being all kept for stock. All kinds of drink is 6d. per glass; porter and ale, 2s. to 3s. per bottle. New milk is 6d. per pint. Firewood, 7s. per cart-load, and that is only for the cartage—the wood costs nothing. Water costs 2s. per week. House rent: I am paying 5s. a week for a hut that would not do for a pigsty in Scotland. Out in the country, however, a house, water, and firewood cost nothing. I had the offer of 30s. a week to fell timber, with my rations, and tent to lodge in; but they would have nothing to do with my wife and children. They wanted twenty men. The trees are all cut three or four feet from the ground."

Correspondence.

*** *We shall be happy to receive early information of general interest from Secretaries of Societies, Clubs, or Institutions, to be addressed to the Editor of the* Working Man, *La Belle Sauvage Yard, Ludgate Hill, London, E.C.*

We do not hold ourselves in any way responsible for the opinions expressed by Correspondents.

A DEFENCE OF TRADES UNIONS.

To the Editor of the Working Man.

Sir,—The seeming bias against Trades Unions, as evidenced in some of the articles on the Labour Question which have appeared in the Working Man, has very naturally given some little umbrage. You have evidently an opinion, and there can be no objection to your right to it; but the responsibility you have is very great to hold a *right* one, and in the investigations and use of it to deal "justly and with judgment" to the parties concerned. Excuse me in saying I do not think that you have done the perfect thing in this matter, in seeing some things too keenly, and apparently not seeing, nor wishing to see, others at all. The faults of the Unions and Unionists you see, and point out very clearly, both by your own remarks, by extracts, and by correspondents; but that the men's leaders are honest, intelligent, faithful, and often right, and that Unions have benefited the members, and obtained advance of wages and improvement of work to the labouring classes in general, I do not remember to have seen any evidence of your knowing. I was, however, glad to see, on Saturday last, in a letter, an extract from Mr. Kettle's "Strikes and Arbitrations," and which (price 1s., very dear, and not likely to get into the hands of working men) gives a hint at the other side of the question, and one overlooked by you in your extract of the 9th—viz., on the injurious results of the bad treatment and want of courtesy shown to workmen by employers. I know the want of even decent manners instanced by your correspondent is not an isolated case. Permit me to add another. In November last, coal was advanced by the Coal Masters' Union in the Barnsley district, at least 20 per cent. on profits. They said this was rendered necessary by the rate of demand; and the colliers—demagogues that they were—took their example, and asked, in November, for a 10 per cent. advance of wages, on the ground that demand for coal was equal to demand for labour, and warranted equally an advance. The written request and the month's notice was duly laid before the Employers' Association, and was, of course, scouted as most unreasonable; and to this day the men's executive have never had an official reply furnished them to their application. A curiously and sinisterly worded anonymous paragraph which appeared in the *Leeds Mercury* next day, stating that the masters had met at Barnsley, and wholly declined to make *any* advance whatever, was all the notice the men had vouchsafed. Of course this led to a strike; a great lock-out was threatened; and ere it came off another effort of the men for an interview was declined, but this time replied to by an attorney, officially. And so another labour struggle followed. Of course the men succeeded; labour was in demand, and the matter was compromised by a "5 per cent. advance and weekly pays" becoming the rule. But it cost thousands to effect what one friendly interview or discussion would have done at once. Now, who were in fault in this matter? Is supply and demand the rule of price? Why, then, not the labourer have its benefits like the masters? Do the masters unite to carry out their own interests and resolutions?—and why not the labourers do the same? And shall the masters appoint officials and executives, with bonds and penalties to enforce conformance, and yet ignore the same action and organisations of the men? Shall Rupert Kettle call John Pot "black face" without John Pot retorting?

The fact is, despite the blame on the false principle of Unions at all, they exist simply as effects of causes, *adequate;* and despite of all vituperation on "leaders and demagogues," they will continue to exist and *flourish* so long as masters treat working men like things, or machinery, to be cheapened or thrown away without consideration, and so long as Rupert Kettle himself admits, within the period of twenty years (?), during which the population of Great Britain and Ireland has doubled itself, capital has increased, upon a *moderate* computation, fivefold, and still goes on, making the relative proportion between these quantities every day greater. Under these circumstances, wages have risen, and will continue to rise until the natural effect of supply and demand has taken its free course, and wages have found their market level. This natural level, the men say, has hitherto been *prevented* by capitalists forming Unions to prevent labour rising to its natural level. Capitalists form Unions *first;* and it is to re-act against the masters' action to retard the natural, level price of supply and demand, and the price of labour, that the men have formed Unions at all. That this should be correctly known, and that the proceedings of the men should be correctly reported, is the great desideratum of the day, and an especial duty of the Working Man to ascertain and publish. Mr. Kettle says workmen *cannot* advance wages by Unions; but the workmen know they *have done so* by union; and the agriculturists, who have no Unions, do not get an advance, though Mr. Kettle asserts wages will rise with wealth. Mr. Kettle says the men keep the proceedings of their Unions secret. The committee appointed by the Association of Social Science to consider the relations of Unions and Combinations, say that the men's agents "came forward with promptness, and in some cases have taken considerable trouble to give the committee accurate information;" but, on the contrary, that "the response on the part of the employers was not so general." The reply to Thomas Hughes, Esq., from the master engineers' solicitor, conveys in one sentence their whole policy, viz.: "I don't think it would be agreeable to the masters generally that any authorised statement of their course of action should be made" (p. 170). Now, here we see the fault charged upon the men's Unions disproved, and, in truth, placed upon Unions of the masters. And this would be the case in most other instances if a dispassionate judge fairly investigated. It would certainly be the case in another false opinion, entertained in quarters where ignorance of the facts, or prejudice, prevails, and to which Mr. Kettle has added another imputation and strength, viz., that the leaders of the men are the restless spirits of their class, worthless as workmen, seeking office for pay, and promoting contentions for personal ends and profit. They are generally deemed ignorant, passionate, and prejudiced, blind leaders of the blind. But this same Social Science committee of gentlemen found out and reported "that, so far as they had been brought into personal connection with societies' officers, their experience is, that the leaders are, for the most part, quite superior to the majority of their fellow-workmen in intelligence and moderation" (p. 15); and, "so far as the committee have been able to learn, the officers of Trades Societies are generally the representatives of their constituencies (p. 16). And perhaps the committee had as good an opportunity of judging of the cases stated as Mr. Kettle, or many another self-elected judge—at least they heard both sides. I could go on at great length thus, repeating and correcting the errors reported on Trades Unions and the laws of their political economy, not a few of which I have seen in the Working Man. Allow me, however, to thank you for publishing what appears to me perfect truth, as the case now stands, in the series of articles on the "Law of Wages," by the Whately Professor of Political Economy. There we have both correct facts and fair reasoning; and I know of few greater boons to be conferred than for these articles to be printed together, and distributed to every master and every workman in Great Britain. Many of both sides are most deplorably ignorant and prejudiced, and the teaching and spirit conveyed would do a world of good to both. Even editors themselves might learn a lesson—at least so thinks yours truly,

John Holms.

Holmville Melkley, near Leeds,
June 19th, 1866.

[We insert the above letter to show that we are desirous of allowing both sides to have an impartial hearing.—Ed. *W. M.*]

TO CORRESPONDENTS.

Apiarian.—If you want your bees to work in the boxes early, give them a good start by cementing a few pieces of clean white comb in each box. It is also an advantage to secure all the corners and cracks of the boxes with a cement composed of ¼ lb. of beeswax and ¾ lb. of rosin. It may be melted and kept at the right temperature by suspending a small tin dish over the chimney of a kerosene lamp. When the boxes are cemented and made tight, it saves the bees much labour, and they are able to get up the requisite heat for comb-building several days sooner.

Apprentice.—The freedom of the City of London is to be obtained in various ways. 1st. By servitude; being bound to a freeman, according to the custom of the City, and serving duly and truly seven years. 2nd. By patrimony; that is, being the son or daughter (unmarried or a widow) of a freeman, born after the admission of the father, and having attained the age of twenty-one years. 3rd. Gift of the City, or honorary freedom. 4th. By redemption or purchase. The admission under this head is as follows:—Persons on the Parliamentary register of voters for the City are admitted upon their application to the Chamberlain (either with or without the interference of a company), and without the usual presentation to the Court for an order. Persons not on the Parliamentary register, but who are £10 householders, and rated to the police and other rates, upon producing a certificate (on their application to the Chamberlain) from the beadle or other authority of their ward that they are so rated, are admitted (with or without the interference of a company) upon the Chamberlain presenting their names to the Court, and obtaining an order for their admission. All the foregoing pay 5s. on their admission, which fee goes to the Freemen's Orphan School. Persons who hold premises, or carry on their business, not having the qualification of either of the two cases before mentioned, are admitted (with or without the interference of a company) upon a fine, including the 5s. to the Freemen's Orphan School, of £2 18s. 4d. Lastly, persons neither holding premises, nor carrying on business within the City or its Liberties, and wishing to become freemen, on their application, can be admitted (either with or without the interference of a company) on the Chamberlain obtaining an order of the Court, on their application. The fine in this case, including the 5s. to the Freemen's Orphan School, is £27 18s. 4d. The sons of aliens, born in England, &c., are now admitted the same as natural-born subjects.

Reader.—Elihu Burritt has given us some particulars respecting John O'Groat. He says that in the reign of James IV., of Scotland, three brothers—Malcolm, Gavin, and John O'Groat—natives of Holland, came to the coast of Caithness, with a letter in Latin to that monarch, recommending them to the protection and countenance of his subjects thereabout. They got possession of a large district of land, and in process of time multiplied and prospered until they numbered eight different proprietors by the name of Groat. On one of the annual dinners, instituted to commemorate their arrival at Caithness, a dispute arose as to the right of precedency in taking the door and the head of the table. This waxed very serious, and threatened to break up these annual gatherings. But the wisdom and virtue of John prevented this rupture. He made a touching speech to them, soothing their angry spirits with an appeal to the common and precious memories of their native land, and to all their joint experiences in this. He entreated them to return to their homes quietly, and he would remedy the current difficulty at the next meeting. Won by his kindly spirit and words, they complied with his request. In the interval, John built a house expressly for the purpose, of an octagonal form, with eight doors and windows. He then placed a table of oak, of the same shape, in the middle, and when the next meeting took place he desired each head of the different Groat families to enter at his own door, and sit at the head of his own table. This happy and ingenious plan restored good feeling and a pleasant footing to the sensitive families, and gave to the good Dutchman's name an interest which it will carry with it for ever.

J. W. A.—The crushing load for flint glass equals about 23,483 lb. per square inch.

NOTICE TO SUBSCRIBERS.

Now ready,

VOL. I. OF THE "WORKING MAN,"

Bound in cloth gilt, price 7s.

TITLE AND INDEX TO VOL. I.,

Price One Penny.

CLOTH CASES FOR BINDING VOL. I.,

Price 1s. 6d.

☞ The next number of the Working Man will be No. 1 of Vol. II., price One Penny, and will be published on Saturday, 7th July. Subscribers are referred to our article at page 408 of the present Number.

Metropolitan and Provincial

WORKING CLASSES' EXHIBITION and INDUSTRIAL FESTIVAL, to be held at the AGRICULTURAL HALL, London, and opened on SEPTEMBER 3rd, 1866.

TO EXHIBITORS.

Contributions of Skilled Workmanship, or Amateur Productions, will be accepted from all parts of London, the Provinces, Scotland, Ireland, and the Colonies. For the benefit of Provincial Exhibitors, the Railway Companies have liberally offered to return unsold goods free, so that the expense of carriage will be but half the usual charge.

NOTICE.—Applications for Space must be forwarded on or before the 30th of June.

SPECIAL PRIZES.

The Council of the above Exhibition have much pleasure in announcing that, in addition to the MEDAL OF MERIT, designed for the occasion by J. S. and A. B. WYON, Esqs., the following SPECIAL PRIZES have been liberally offered by the gentlemen named, for the production of Articles to be Exhibited at the Agricultural Hall in September next, namely—

£15 0 0 in Money, or Silver Cup, for the MOST USEFUL INVENTION. Open to all Classes. The Gift of the Directors of the Agricultural Hall Company.

£10 0 0 in Money, or Silver Cup, for the best PAINTING IN OIL. The Gift of the Directors of the Agricultural Hall Company.

Happy Homes for Working

MEN, AND HOW TO GET THEM. By the Rev. Dr. BEGG. Price, in paper covers, 1s. 6d.; bound in cloth, 2s. London: Cassell, Petter, and Galpin, Ludgate Hill, E.C. Edinburgh: James Nichol.

Gathered from the Waters.

For ages past there have been running from the various mines in Cornwall large streams of water. About the year 1837, it occurred to a miner to test one of the streams to see if it contained Copper: it was found very productive. Since that the works have been carried on successfully, and now 100 tons of Copper, or more, are gathered from the water every year. The works have undergone the examination of many experienced persons, and a Company has been formed to work the streams upon scientific principles. The Company seeks to acquire the right to work the whole of one large stream, and desires to secure some additional Capital for the purpose. The Company is formed upon the principle of Limited Liability. There is no risk whatever in carrying on the works, and the profit is known to be very large, and certain of making good Dividends for the Shareholders. The Shares are of £5 each, but only £1 is called—10s. on application, and 10s. on allotment. More than £3,600 is subscribed for privately, and early application should be made for the remaining Shares. Any one desiring a safe and profitable investment cannot do better than take Shares in this Company.

Fuller information can be obtained from the Secretary of the Copper Precipitating Company (Limited), Office, 8, Warnford Court, Throgmorton Street, London, E.C.

The Planet Permanent Building and Investment Society, Established by Act of Parliament, July, 1848. Annual Income exceeds £200,000. Offices, 39, CITY ROAD, FINSBURY SQUARE, LONDON, E.C. The SEVENTEENTH ANNUAL MEETING was held September 12th, 1865. The Directors reported a large Augmentation of Business, and an Accumulation of Profits, which allowed a Bonus of £10 per cent., making the Dividend for the past year £15 per cent. The sum of £12,505, the Balance of Profit, had been carried forward for future division. The Assets of the Society had been increased during the year by £106,981. The Directors confidently reaffirm that—first, as a mode of investment at once secure and profitable; secondly, in the easy terms to Borrowers, and the facilities afforded for their transactions; thirdly, in the Equitable Adjustment of Repayment and Interest; fourthly, in the mode of Redemption; and, lastly, in the moderate fixed Law and other Charges, this Society stands alone. Shares, £50; Entrance Fee, 2s. 6d. per Share. Deposits to any amount—upon which no entrance fee is charged—may be made. Interest, £5 per cent., repayable on fourteen days' notice. Prospectuses and all further information may be had of EDMUND W. RICHARDSON, Secretary.
Offices—39, City Road, London, E.C. [13

B. Prew's Wardrobe.

At this splendid new building you'll see a display
Of all the new fashions, the first of the day;
If well dress'd you'd be, and at lowest price, too,
"Then come to my wardrobe," says Benjamin Prew.

If frock or Oxonian you should require,
And really are choice in this part of attire,
Wishing best of material, with style that is new,
"Then come to my wardrobe," says Benjamin Prew.

If a coat you should want, for business or dress,
Or a waistcoat of which you'd approval express,
Or trousers to fit, cut on system quite new,
"Then come to my wardrobe," says Benjamin Prew.

If you have any boys, and would see them well dressed,
In clothes to wear well, and become them the best;
Or want Knickerbocker suits for young children, too,
"Then come to my wardrobe," says Benjamin Prew.

Every one buys of Prew, so well known is his name.
If you study your int'r'st you'll just do the same;
If you'd dress in the fashion, and save money, too,
"Then come to my wardrobe," says Benjamin Prew.

Children's Knickerbocker Suits from	12s. 6d.
Boys' Eton, Harrow, and Rugby Suits	21s. 0d.
Boys' Cricketing Suits	21s. 0d.
Gentlemen's Overcoats, from	12s. 6d.
Ladies' Riding Habits, Liveries, &c.	

B. PREW, Tailor, Hatter, Hosier, and General Outfitter, the great Metropolitan Wardrobe, 294 and 295, High Holborn (15 doors west of Chancery Lane). [17

Sec.* [23

The Original Chlorodyne, Invented by R. FREEMAN, Pharmaceutist, is allowed to be one of the greatest discoveries of the present century. It immediately relieves and cures Coughs, Colds, Consumption, Influenza, Bronchitis, Asthma, Whooping Cough, Cramp, Spasms, Gout, Diarrhœa, Dysentery, &c.
EARL RUSSELL communicated to the Royal College of Physicians and to Mr. Freeman that he had received information from Manilla that the only remedy of any use in Cholera was Chlorodyne.—*Lancet*, Dec. 31st, 1864. See *Times*, Nov. 14th, 1865.

Freeman's Original Chlorodyne.—The *Medical Times*, Jan. 13th, 1866, states—"It has an immense sale amongst the public, and is prescribed by scores of orthodox medical practitioners, and, of course, it would not be thus singularly popular did it not supply a want and fill a place."

Freeman's Original Chlorodyne engraved on the Government stamp outside every bottle. Sold by the Inventor and Manufacturer, R. FREEMAN, 70, Kennington Park Road, London, S., and most Chemists. In bottles, ¼ oz., 1s. 1½d.; 1½ oz., 2s. 9d.; 10 oz., 11s.; 20 oz., 20s.
Caution! Beware of spurious, deceptive, and dangerous imitations. Ask for Freeman's Original Chlorodyne, and see that you have none other. [24

Holloway's Pills purify the Blood, and by so doing prevent the depressing effects of hot, dusty, and oppressive weather. They rouse the nervous system to a healthy standard, and give a wholesome tone to every organ in the body. Holloway's Pills constitute the surest means of checking all chest complaints. [32

Hall's "Lung Restorer" gives instant relief in Coughs, Asthma, Hoarseness, Sore Throat, &c. Mr. R. Brooke, Mirfield, near Leeds, writes, after suffering over ten years with an asthmatic cough, "Three 1s. 1½d. bottles cured me." Prepared by THOMAS HALL, Chemist, 6, Commercial Street (City side Great Eastern Terminus), London, and sold by all Chemists, in bottles, at 1s. 1½d., 2s. 9d., &c. [25
